OGRe: An **O**bject-oriented **G**eneral **Re**lativity Package for Mathematica

By Barak Shoshany (baraksh@gmail.com) (baraksh.com) Documentation for v1.1 (April 15, 2021) https://github.com/bshoshany/OGRe

Introduction

Summary

OGRe is a modern Mathematica package for tensor calculus, designed to be both powerful and user-friendly. It can be used in a variety of contexts where tensor calculations are needed, in both mathematics and physics, but it is especially suitable for general relativity.

Tensors are abstract objects, which can be represented as multi-dimensional arrays once a choice of index configuration and coordinate system is made. OGRe stays true to this definition, but takes away the complexities that come with combining tensors in different representations. This is done using an object-oriented programming approach, as detailed in the documentation.

The user initially defines each tensor in OGRe using its explicit components in any single representation. Operations on this tensor are then done abstractly, without needing to specify which representation to use. Possible operations include addition of tensors, multiplication of tensor by scalar, trace, contraction, and partial and covariant derivatives.

OGRe will automatically choose which representation to use for each tensor based on how the tensors are combined. For example, if two tensors are added, then OGRe will automatically use the same index configuration for both. Similarly, if two tensors are contracted, then OGRe will automatically ensure that the contracted indices are one upper (contravariant) and one lower (covariant). OGRe will also automatically transform all tensors being operated on to the same coordinate system.

Transformations between representations are done behind the scenes; all the user has to do is specify which metric to use for raising and lowering indices, and how to transform between the coordinate systems being used. This also means that there is no room for user error. The user cannot mistakenly perform "illegal" operations such as $2 A^{\mu\nu} + B_{\mu\lambda} C_{\lambda\nu}$. Instead, the user simply inputs the names of the tensors, the order (but **not** the configuration) of indices for each, and the operations to perform - and the correct combination $2 A^{\mu\nu} B^{\mu}_{\lambda} C^{\lambda\nu}$ will be automatically deduced.

I initially created OGRe for use in my own research, so I made it as flexible and powerful as possible. I also wanted my students to be able to use it easily and efficiently, even if they only have minimal experience with Mathematica and/or general relativity, so I made it simple to learn and easy to use. As a result, this package is equally suitable for both experienced and novice researchers.

Features

- Define coordinate systems and the transformation rules between them. Tensor components are then transformed automatically between coordinates behind the scenes as needed.
- Each tensor is associated with a specific metric. Tensor components are then transformed automatically between different index configurations, raising and lowering indices behind the scenes as needed.
- Display any tensor in any index configuration and coordinate system, either in vector/matrix form or as a list of all unique non-zero elements.
- Automatically simplify tensor components, optionally with user-defined simplification assumptions.
- Export tensors to a Mathematica notebook or to a file, so they can later be imported into another Mathematica session without having to redefine them from scratch.
- Easily calculate arbitrary tensor formulas using any combination of addition, multiplication by scalar, trace, contraction, partial derivative, and covariant derivative.
- Built-in modules for calculating the Christoffel symbols (Levi-Civita connection), Riemann tensor, Ricci tensor and scalar, and Einstein tensor. More will be added in future versions.
- Fully portable. Can be imported directly from the web into any Mathematica notebook, without downloading or installing anything.
- Clear and detailed documentation, with many examples, in both Mathematica notebook and PDF format. Detailed usage messages are also provided.
- Open source. The code is extensively documented; please feel free to fork and modify it as you see
- Under active development. Please see the "future plans" section of the documentation for more information. Bug reports and feature requests are welcome, and should be made via GitHub issues.

The object-oriented design philosophy

Object-oriented programming refers to a paradigm where a program's code is organized around objects. An object belongs to a user-defined type, called a class. The class defines the data that the object stores, as well as methods or member functions that read or manipulate that data. One of the fundamental principles of object-oriented programming is encapsulation, which means that the user may only access an object's data using the methods defined by the class, and is unable to access the object's data directly.

Importantly, encapsulation allows for the preservation of class invariants. An invariant is a condition of validity that can always be assumed to be satisfied by the data stored in each object. If the methods make sure to preserve the invariant whenever they store or manipulate the data, and the user is prevented from changing the data manually and thus potentially violating the invariant, then the implementation of the class can be greatly simplified, and performance can be improved, because we will not need to verify that the data is valid every time we perform an operation.

The main idea behind OGRe is to simplify the use of tensors by encoding all the information about a tensor in a single, self-contained object. As we mentioned above, a tensor is an abstract object. We can find components which represent this abstract entity in a particular coordinate system and index configuration, but the tensor is **not** its components. In OGRe, a tensor object is initially defined (or constructed) by providing the components of the tensor in a particular representation - but once this is done, the user does not need to worry about coordinates or indices anymore, or even remember which coordinates and indices were initially used. The abstract tensor object will automatically transform the initial data to a different coordinate system or index configuration as needed, based on the context in which it was used.

As a tensor object holds the components of the same tensor in many different representations, the most important class invariant is the assumption that the different components indeed represent the same tensor. This is achieved using encapsulation; the object's data can only be modified by private methods that preserve the invariant, and thus the user cannot accidentally cause a violation of the invariant by assigning components to one representation that are not related to the components of all other representations by the appropriate coordinate and/or index transformation.

Unfortunately, Mathematica does not have built-in support for object-oriented programming. However, version 10.0 of Mathematica, released in 2014, introduced the Association symbol. An Association is an associative array; it is similar to a List, except that instead of being just an array of values, an Association is a list of keys with a value associated to each key. This allows us to easily implement a rudimentary form of object-oriented programming, storing the properties of each object in the keys of a corresponding Association.

Of course, as Mathematica is not truly object-oriented, there is no actual "tensor class" defined anywhere in the package. Instead, the tensor class exists only implicitly, as a design paradigm. Furthermore, the functions that process the data stored in the tensor objects are not methods of a class, they are simply modules that take tensor objects as input and/or produce tensor objects as outputs. (In earlier versions, I tried using a syntax that resembled method syntax in languages such as C++ or Python, but eventually decided against it, as it was too cumbersome.) Still, designing the package with object-oriented programming in mind allows us to reap many of this paradigm's benefits, as explained above - and it simply makes sense for tensors, due to their abstract and multifaceted nature.

Installing and loading the package

The package consists of only one file, OGRe.m. There are several different ways to load the package:

■ Run from local file with installation: This is the recommended option, as it allows you to permanently use the package offline from any Mathematica notebook. Download the file OGRe.m from https://github.com/bshoshany/OGRe and copy it to the directory given by FileNameJoin[{\$UserBaseDirectory,"Applications"}]. The package may now be loaded from any notebook by writing Needs ["OGRe"] (note the backtick following the word OGRe).

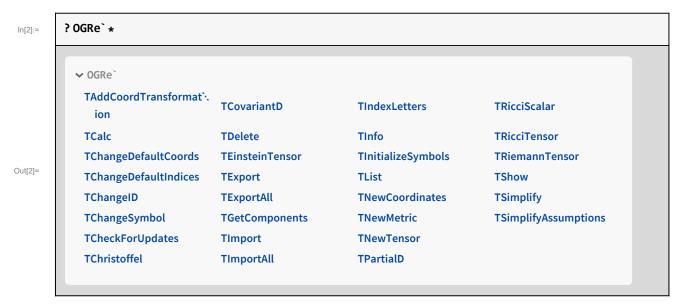

- Run from local file without installation: This option allows you to use the package in a portable fashion, without installing it in the Applications directory. Download the file OGRe.m from https://github.com/bshoshany/OGRe, place it in the same directory as the notebook you would like to use, and use the command Get ["OGRe.m", Path→NotebookDirectory[]] to load the package.
- Run from web with installation: This option allows you to automatically download and install the package on any computer. Simply run the command URLDownload["https://raw.githubusercontent.com/bshoshany/OGRe/master/OGRe.m",FileNameJo in[{\$UserBaseDirectory,"Applications","OGRe.m"}]] from any Mathematica notebook to permanently install the package. Then use Needs ["OGRe"] from any notebook to load it.
- Run from web without installation: This option allows you to use the package from any Mathematica notebook on any computer, without manually downloading or installing it, as long as you have a working Internet connection. Simply write Get["https://raw.githubusercontent.com/bshoshany/OGRe/master/OGRe.m"] in any Mathematica notebook to load the package.

To uninstall the package, just delete the file from the Applications directory, which can be done from within Mathematica the using command DeleteFile[FileNameJoin[{\$UserBaseDirectory,"Applications","OGRe.m"}]].

For the purposes of this documentation, I will use the "run from local file without installation" option, since you most likely downloaded both the documentation and the package together:

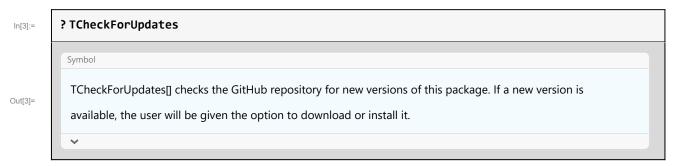

```
Get["OGRe.m", Path → NotebookDirectory[]]
In[1]:=
       OGRe: An (0) bject-oriented (G) eneral (Re) lativity Package for Mathematica
       By Barak Shoshany (baraksh@gmail.com) (baraksh.com)
       v1.1 (April 15, 2021)
       GitHub repository: https://github.com/bshoshany/OGRe
       To automatically check if a new version is available, type
       TCheckForUpdates[] or click here.
       To list all available modules, type ?OGRe`* or click here.
       To get help on a particular module, type ? followed by the module name.
```

The package displays a welcome message upon loading, which provides some information on how to get started. As stated in the welcome message, to list all of the modules available in this package, you may use the following command:

Clicking on the name of any module in this list will show its usage message. Notice that all OGRe modules start with the letter T, to help distinguish them from other modules, whether built-in or from other packages.

If you are running the package from a local file, it is recommended to periodically use the module TCheckForUpdates to check the GitHub repository for updates. If a new version of the package has been released, you will be given the option to download or install it in one click. If you are running the package directly from the web, you will always be using the latest version.

Creating and displaying tensor objects

Defining coordinates

To define tensors, we first need to define the manifold on which they reside. Since we are focusing on general relativity, we will use 4-dimensional spacetime manifolds in the following examples, but this package works equally well with manifolds that are purely spatial and/or have a different number of dimensions.

The first step is to define the coordinate system. In OGRe, coordinates are represented as a special

tensor object: a vector x^{μ} (a tensor of rank 1) representing a point. To define the coordinates, we use the module TNewCoordinates:

? TNewCoordinates In[4]:= Symbol TNewCoordinates[coordinatesID, symbols] creates a new tensor object representing a coordinate system. coordinatesID is a string that will be used to identify the new object, and must be unique. If a tensor object Out[4]= with the same ID already exists, it will be overwritten. symbols are the coordinate symbols, e.g. {t, x, y, z}. They will automatically be cleared and protected against future changes using TInitializeSymbols[].

For example, to define the **Cartesian coordinate system**, we use the following syntax:

TNewCoordinates["Cartesian", {t, x, y, z}] In[5]:= Cartesian Out[5]=

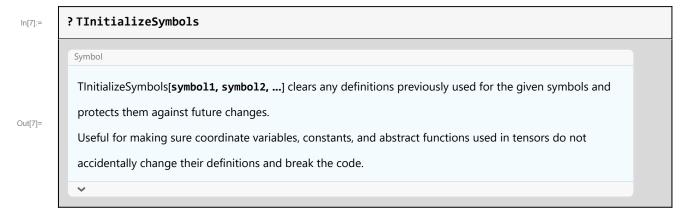

The first argument is the new tensor object's **unique ID**. This is the string that we will use to refer to this tensor from now on, and it will also be displayed whenever we print the tensor. The ID string is casesensitive, can include any characters, and can be of any length, but it is recommended to keep it short and simple. If we create another tensor object with the same ID, the previous definition will be overwritten. Note that the ID string is also the return value of the module; generally, all modules that operate on a tensor object will return its ID string as output. This allows us to compose different modules together, as we will see below.

The second argument is the list of coordinates. Note that the order of coordinates matters, as it will determine the order of components in the tensors defined on this manifold. The symbols used also matter, as tensor components will usually be functions of these symbols. We can similarly define the spherical coordinate system:

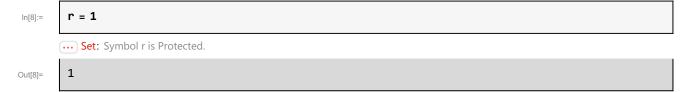

```
TNewCoordinates["Spherical", \{t, r, \theta, \phi\}]
In[6]:=
         Spherical
Out[6]=
```

It is crucial that the coordinate symbols, in this case t, r, θ, ϕ , remain as **undefined** symbols throughout the calculation, otherwise errors may occur. For example, if our metric contains functions of r, and at some point in the notebook we set r = 1, then Mathematica will replace every instance of r with 1, which means those abstract functions will be replaced with their values evaluated at r = 1. Furthermore, if we, for example, want to take the derivative with respect to r (e.g. for the purpose of calculating various curvature tensors), this will not be possible, since one cannot take a derivative with respect to a number.

To prevent such errors, TNewCoordinates automatically clears any previous definitions of the given symbols, and also protects them against future changes. This is done using the TInitializeSymbols module:

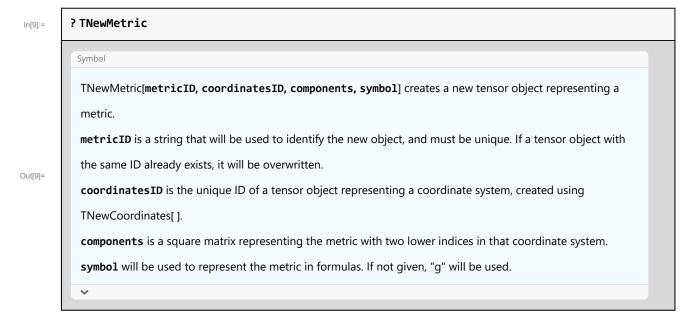

Indeed, if we now try to give r the value 1, we will get an error:

You can also use TInitializeSymbols manually for any constants or parameters used in the tensor, as we will demonstrate in the next section. Note that it is always possible to replace protected symbols with numbers or other expressions using /. or ReplaceAll.

Defining metrics

To finish defining a manifold, we need to define its metric tensor. For this, we use the module TNewMetric:

Again, we must input a unique ID for the new tensor object corresponding to the metric. We also input the unique ID of a coordinate system created using TNewCoordinates. This coordinate system is the one in which the components of the metric are initially given, but they will be automatically transformed to other coordinate systems later as needed. Note that the components are assumed to be the representation of the metric with two lower indices, since that is how metrics are usually defined; one upper and one lower index is just the identity matrix, and two upper indices is the inverse metric. Optionally, we can also specify a symbol to be used for representing the metric.

Let us use this module to create a tensor object for the **Minkowski metric**, specifying the components in Cartesian coordinates:

```
TNewMetric["Minkowski", "Cartesian", DiagonalMatrix[\{-1, 1, 1, 1\}], "\eta"]
In[10]:=
         Minkowski
Out[10]=
```

As with TNewCoordinates, we received the ID string for the new tensor object as output.

Similarly, let us define the Schwarzschild metric, this time specifying the components in spherical coordinates. However, before we can safely do so, we should take one additional step. When we defined the coordinates using TNewCoordinates, the symbols used were automatically initialized, that is, cleared and protected from future changes, using TInitializeSymbols. However, TNewMetric does not automatically initialize symbols. Since the Schwarzschild metric has a free parameter M, the mass of the black hole, we must initialize this symbol manually:

TInitializeSymbols[M]

In[11]:=

Now we can define the Schwarzschild metric:

TNewMetric ["Schwarzschild", "Spherical",
DiagonalMatrix
$$\left[\left\{-\left(1-\frac{2\,\mathrm{M}}{r}\right),\,\frac{1}{1-\frac{2\,\mathrm{M}}{r}},\,r^2,\,r^2\,\mathrm{Sin}\left[\theta\right]^2\right\}\right]\right]$$

Out[12]=

Schwarzschild

Note that since we do not specify a symbol, the symbol "g" will be used by default, as demonstrated below.

Displaying tensors

OGRe contains two modules for displaying the contents of tensors. The first one is TShow, which shows the ID, symbol, indices, coordinates, and components in those indices and coordinates, in vector or matrix form when applicable:

In[13]:=

? TShow

Symbol

TShow[ID, indices, coordinatesID] shows the components of the tensor object ID with the index configuration indices and in the coordinate system coordinatesID, in vector or matrix form when applicable.

Out[13]=

indices should be a list of the form {±1, ±1, ...}, where +1 corresponds to an upper index and -1 corresponds to a lower index.

If the index configuration and/or coordinate system are omitted, the default ones will be used.

Coordinates are also tensor objects, so we can use TShow to show the two coordinate tensors we defined above:

In[14]:=

TShow["Cartesian"]

Out[14]=

Cartesian:
$$x^{\mu} = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

In[15]:=

TShow["Spherical"]

Spherical: $x^{\mu} = \begin{pmatrix} r \\ r \\ \theta \\ dr \end{pmatrix}$

Out[15]=

Note that coordinate tensors always have the symbol x.

We can also show the two metrics we created using these coordinates:

In[16]:=

TShow["Minkowski"]

Minkowski: $\eta_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Out[16]=

TShow["Schwarzschild"]

Schwarzschild: $g_{\mu\nu}(t, r, \theta, \phi) = \begin{pmatrix} -1 + \frac{2M}{r} & 0 & 0 & 0 \\ 0 & \frac{1}{1 - \frac{2M}{r}} & 0 & 0 \\ 0 & 0 & r^2 & 0 \\ 0 & 0 & 0 & r^2 \sin[\theta]^2 \end{pmatrix}$

The other module available in OGRe for displaying the contents of tensors is TList, which lists all of the unique (up to sign), non-zero components of the tensor. It is usually the best option for higher-rank tensors, which cannot be displayed in vector or matrix form, such as the Christoffel symbols or Riemann tensor (see below). Its syntax is:

In[17]:=

Out[17]=

In[18]:=

Out[18]=

?TList

Symbol

TList[ID, indices, coordinatesID] lists the unique, non-zero components of the tensor object ID with the index configuration indices and in the coordinate system coordinatesID.

indices should be a list of the form {±1, ±1, ...}, where +1 corresponds to an upper index and -1 corresponds to a lower index.

If the index configuration and/or coordinate system are omitted, the default ones will be used.

For example:

In[19]:=

TList["Minkowski"]

Out[19]=

$$\eta_{\text{tt}} = -\eta_{\text{xx}} = -\eta_{\text{yy}} = -\eta_{\text{zz}} = -1$$

In[20]:=

Out[20]=

TList["Schwarzschild"]

Schwarzschild:

$$g_{tt} = -1 + \frac{2M}{r}$$

$$g_{rr} = \frac{1}{1 - \frac{2M}{r}}$$

$$g_{\theta\theta} = r^2$$

$$g_{\theta\theta} = r^2$$

 $g_{\phi\phi} = r^2 \sin[\theta]^2$

Note that both TShow and TList display their outputs using the DisplayFormula Notebook style. It's up to the user to decide how to define this style; in this notebook, I used a font size of 20 and aligned to center. The style may be easily changed by clicking on the "Format" menu in Mathematica and selecting "Edit Stylesheet". Then, choose the DisplayFormula style, select that cell, and modify its format using the "Format" menu.

If, as in the examples above, no additional arguments are given to TShow and TList, they display the tensors in their default indices and default coordinates, which are the ones first used to define the tensor (unless you change them later). So, for example, the default indices of the Minkowski metric are two lower indices, and its default coordinates are Cartesian. We will show later how to change these defaults, and how to display any tensor in any index configuration and coordinate system.

By default, the TShow module uses Greek letters for the indices, in a specific order. The letters can be

displayed or changed using the TIndexLetters module:

? TIndexLetters In[21]:= Symbol TindexLetters[letters] changes the letters to be used when displaying indices. Out[21]= If **letters** is omitted, shows the index letters currently in use. If **1etters** is set to Automatic, resets the index letters to the default (lowercase Greek letters).

The default letters are:

TIndexLetters[] In[22]:= μνρσκλαβγδεζεθιξπτφχψω Out[22]=

This means that the letter μ will be used for the first index, ν for the second, and so on. However, sometimes we want to use different letters. For example, let us change the indices to lowercase English letters:

TIndexLetters["abcdefghijklmnopqrstuvwxyz"] In[23]:=

"Show" will now use these letters - in this particular order - when displaying tensors:

TShow["Minkowski"] In[24]:= Minkowski: $\eta_{ab}(t, x, y, z) = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$ Out[24]=

Finally, let us reset the letters to the default:

TIndexLetters[Automatic] In[25]:=

Note that TList always uses the coordinate symbols for the indices, so it is not affected by TIndexLetters.

Creating tensors in a given manifold

Any tensors other than coordinates and metrics are created using the module TNewTensor:

In[26]:=

? TNewTensor

Symbol

TNewTensor[tensorID, metricID, coordinatesID, indices, components, symbol] creates a new tensor object.

tensorID is a string that will be used to identify the new object, and must be unique. If a tensor object with the same ID already exists, it will be overwritten.

metricID is the unique ID of a tensor object representing a metric, created using TNewMetric[]. The metric will be used to raise and lower indices for the new tensor.

coordinatesID is the unique ID of a tensor object representing a coordinate system, created using TNewCoordinates[]. This coordinate system will be used to specify the components of the new tensor. If omitted, the default coordinate system of the metric metricID will be used instead.

indices is a list of the form {±1, ±1, ...}, where +1 corresponds to an upper index and -1 corresponds to a lower index.

components is a list specifying the representation of the tensor with the index configuration indices and in the coordinate system coordinatesID.

symbol will be used to represent the tensor in formulas. If not given, the placeholder □ will be used.

In OGRe, all tensor objects must have an associated metric - except coordinate objects, and the metric tensors themselves. This is because OGRe automatically raises and lowers indices as appropriate for various operations such as adding and contracting tensors, and it cannot do so without knowing which metric to use. Even scalars, which have no indices, should still be associated to a specific metric - since they can multiply other tensors, and you don't want to multiply tensors from different manifolds together.

The index configuration of the tensor is a 1-dimensional List. The number of indices is the rank of the tensor. Each element in the List corresponds to one index, with +1 specifying an upper index and -1 specifying a lower index. For example, $\{-1,-1\}$ corresponds to a tensor such as the metric $g_{\mu\nu}$, which has two lower indices, while $\{1,-1,-1,-1\}$ corresponds to a tensor such as the Riemann tensor $R^{\rho}_{\sigma u \nu}$, which has one upper index followed by three lower indices.

The components of the tensor must also be a **List**. The components are the representation of the new tensor in the given index configuration and coordinate system. If a coordinate system is not specified, the default coordinate system of the associated metric will be used - but it is recommended to always specify the coordinate system explicitly, to avoid accidentally defining the tensor with the wrong components. The components will be automatically converted to different indices or coordinates later as needed, as we will demonstrate below.

Out[26]=

To create a **scalar**, or a tensor of rank 0 (with no indices), we must input an empty list {} for the indices, and a list with one item for the components. For example, let us define the Kretschmann scalar in the Schwarzschild spacetime (below we will show how to calculate it directly from the metric):

TNewTensor["Kretschmann", "Schwarzschild", "Spherical",
$$\{\}$$
, $\left\{\frac{48 \text{ M}^2}{r^6}\right\}$, "K"]

Kretschmann Out[27]=

Again, the output is the unique ID of the tensor object that was created. Let us show the tensor:

TShow["Kretschmann"]

Kretschmann: K $(t, r, \theta, \phi) = \frac{48 M^2}{r^6}$

Notice that the output of TNewTensor is also the input of TShow, so in fact, we could compose them together using @. We will do so from now on.

Similarly, we can create a **vector**, or a tensor of rank 1 (with one index). For example, let us create a vector for the 4-velocity of a particle moving at 3-velocity v along the x direction in Minkowski space. First we initialize the parameter representing the velocity:

TInitializeSymbols[v]

Since the 4-velocity has an upper index by definition, we make sure to define the components in the representation of the tensor with an upper index by specifying the index configuration as {1}:

$$TShow@TNewTensor\Big["FourVelocity", "Minkowski", "Cartesian", \{1\}, \frac{\{1, v, 0, 0\}}{\sqrt{1-v^2}}\Big]$$

FourVelocity: $\square^{\mu}(t, x, y, z) = \begin{bmatrix} \frac{1}{\sqrt{1-v^2}} \\ \frac{v}{\sqrt{1-v^2}} \\ 0 \end{bmatrix}$

Again, the output of TNewTensor was the ID of the tensor, "FourVelocity", but that is also the input we want to pass to TShow, so we composed the two modules together. Note also that since we did not specify a symbol for this tensor, its symbol is just a placeholder □. We will give it a proper symbol below.

Finally, as an example of a tensor of rank 2 (with two indices), let us define the stress-energy tensor $T^{\mu\nu}$ for a perfect fluid. First, let us initialize the symbols ρ (for the energy density) and \mathbf{p} (for the pressure):

In[28]:=

In[27]:=

Out[28]=

In[30]:=

In[29]:=

Out[30]=

TInitializeSymbols $[\rho, p]$ In[31]:=

> Next we create the tensor, using its matrix representation with two upper indices by specifying the index configuration {1,1}:

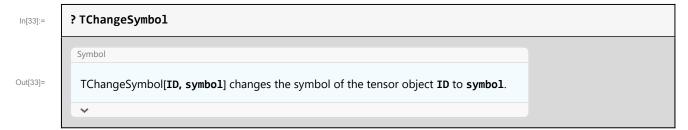

TShow@TNewTensor["PerfectFluid", "Minkowski", In[32]:= "Cartesian", $\{1, 1\}$, DiagonalMatrix $[\{
ho, p, p, p\}]$, "T"] PerfectFluid: $T^{\mu\nu}(t, x, y, z) = \begin{pmatrix} \rho & 0 & 0 & 0 \\ 0 & \rho & 0 & 0 \\ 0 & 0 & \rho & 0 \\ 0 & 0 & 0 & \rho \end{pmatrix}$ Out[32]=

In a similar manner, we could also define tensors of rank 3 and above. However, such tensors are most often derived by operating on lower-rank tensors, rather than defined manually via their components. We will see an example of such a derivation when we derive the Christoffel symbols and Riemann tensor from the metric below.

Operations on single tensors

Changing the symbol or ID of a tensor

If we ever want to change the symbol used to display a tensor, we can simply use the module TChangeSymbol:

For example, let us give the symbol u to the four-velocity, and then show it:

Out[34]=

TShow@TChangeSymbol["FourVelocity", "u"]

FourVelocity:
$$u^{\mu}(t, x, y, z) = \begin{pmatrix} \frac{1}{\sqrt{1-v^2}} \\ \frac{v}{\sqrt{1-v^2}} \\ 0 \\ 0 \end{pmatrix}$$

Similarly, we can also change the ID of the tensor using the TChangeID module:

In[35]:=

Out[35]=

? TChangeID

Symbol

TChangelD[oldID, newID] changes the ID of the tensor object oldID to newID.

If the tensor is a metric or a coordinate system, all currently defined tensors will be scanned, and any references to **oldID** will be replaced with **newID**. If a tensor with the ID **newID** already exists, it will be overwritten.

~

For example, let us change the ID of the 4-velocity tensor from "FourVelocity" to "4-Velocity":

In[36]:=

TChangeID["FourVelocity", "4-Velocity"];

The old ID no longer represents any tensor object, so we get an error if we try using it:

In[37]:=

TShow["FourVelocity"]

OGRe`Private`CheckIfTensorExists: The tensor "FourVelocity" does not exist.

Out[37]=

\$Aborted

We can access the tensor using the new ID:

In[38]:=

TShow["4-Velocity"]

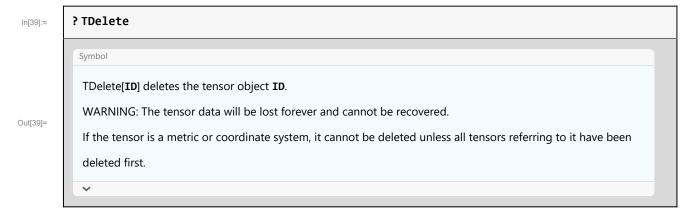

Out[38]=

4-Velocity:
$$u^{\mu}(t, x, y, z) = \begin{pmatrix} \frac{1}{\sqrt{1-v^2}} \\ \frac{v}{\sqrt{1-v^2}} \\ 0 \\ 0 \end{pmatrix}$$

Note that when we define a tensor using a metric and a coordinate system, OGRe doesn't store the actual metric components or coordinates inside the tensor object - it only stores **references** to the

relevant objects, using their IDs. This both improves performance and allows us to modify the metric or coordinates later without having to redefine all the tensors derived from them. For this reason, if the tensor to be renamed represents a metric or a coordinate system, OGRe will automatically update the references in the definitions of all of the tensors that have been defined so far in the session using that metric or coordinate system. This guarantees that there are never any broken references.

If we want to delete a tensor we have created, we can use the TDelete module:

To prevent breaking references, TDelete will not delete a tensor object representing a metric or coordinate system if it is referred to by any other tensor. For example, if we try to delete the coordinate system "Cartesian", we will get an error message, since it is used as the default coordinate system for "Minkowski" (among others):

TDelete: The coordinate system "Cartesian" cannot be deleted, as it is the default coordinate system of the tensor "Minkowski". To delete the coordinate system, first change the default coordinate system of "Minkowski" and any other relevant tensors.

\$Aborted Out[40]=

Out[41]=

Similarly, we cannot delete the metric "Minkowski" since it was used to define the tensor "PerfectFluid" (among others):

TDelete["Minkowski"] In[41]:=

TDelete: The metric "Minkowski" cannot be deleted, as it has been used to define the tensor "PerfectFluid". To delete the metric, first delete "PerfectFluid" and any other tensors defined using this metric.

\$Aborted

Finally, note that there is no module to change the components of a tensor after it has already been defined, as this may break class invariants. Instead, simply create a new tensor with the same ID using the TNewTensor module, which will overwrite the previously defined tensor.

Raising and lowering indices

Raising and lowering indices is one of the most basic tensor operations. For example, if we have a vector represented with one upper index, \mathbf{v}^{\vee} , we can turn it into a covector, which is represented with one lower index, by **contracting** it with the metric:

$$\mathbf{v}_{\mu} = \mathbf{g}_{\mu\nu} \mathbf{v}^{\nu}$$
.

This is called "lowering an index". Here and in the rest of this documentation, we will be using the Einstein summation convention, where the same index repeated exactly twice, once as an upper index and once as a lower index, implies summation over that index. In this case, the implied summation is over $v \in \{0, 1, 2, 3\}$:

$$v_{\mu} = \sum_{\nu=0}^{3} g_{\mu\nu} v^{\nu} = g_{\mu0} v^{0} + g_{\mu1} v^{1} + g_{\mu2} v^{2} + g_{\mu3} v^{3}$$
.

Such a sum over an index is called a contraction, and it is a generalization of the inner product, as we will describe in more details below. Conversely, if we have a covector \mathbf{w}_{μ} , we can raise its index by contracting it with the inverse metric:

$$\mathbf{w}^{\mu} = \mathbf{g}^{\mu\nu} \mathbf{w}_{\nu}$$
.

This works the same for indices of higher-rank tensors. For example, if we have a tensor of rank 2 represented with two upper indices, $T^{\mu\lambda}$, we can lower either one or both of its indices:

$$T^{\mu}_{\nu} = g_{\nu\lambda} T^{\mu\lambda}$$
, $T_{\mu\nu} = g_{\mu\rho} g_{\nu\lambda} T^{\rho\lambda}$.

In OGRe, since tensor objects are **abstract tensors**, independent of any specific index configuration, there is no notion of raising or lowering the indices of a tensor object. Instead, one simply request to display the components of the tensor with the desired index configuration. This works with both the TShow and TList modules, by simply adding as a second argument the list of indices in the format $\{\pm 1, \pm 1, \ldots\}$, as when we created a new tensor.

As an example, let us show the vector "4-Velocity" with a lower index, that is, with index configuration {-1}:

TShow["4-Velocity", {-1}]

4-Velocity:
$$u_{\mu}(t, x, y, z) = \begin{pmatrix} -\frac{1}{\sqrt{1-v^2}} \\ \frac{v}{\sqrt{1-v^2}} \\ 0 \\ 0 \end{pmatrix}$$

OGRe automatically knows to use the Minkowski metric to lower the index, which means that a minus

In[42]:=

Out[42]=

sign has been added to the first component, as expected. Similarly, let us lower just the second index on PerfectFluid:

In[43]:=

TList["PerfectFluid", {1, -1}]

PerfectFluid:

Out[43]=

$$T_{t}^{t} = -\rho$$
 $T_{x}^{x} = T_{y}^{y} = T_{z}^{z} = \rho$

The components of the representation of the metric with two upper indices are the components of the inverse metric, since

$$\mathbf{g}_{\mu\lambda} \mathbf{g}^{\lambda\nu} = \delta_{\mu}^{\nu}$$
.

Therefore, a quick way to show the components of the inverse metric is:

In[44]:=

TShow["Schwarzschild", {1, 1}]

hwarzschild", {1, 1}]
$$Schwarzschild: g^{\mu\nu}(t, r, \theta, \phi) = \begin{pmatrix} \frac{r}{2M-r} & 0 & 0 & 0 \\ 0 & 1 - \frac{2M}{r} & 0 & 0 \\ 0 & 0 & \frac{1}{r^2} & 0 \\ 0 & 0 & 0 & \frac{\csc[\theta]^2}{r^2} \end{pmatrix}$$

Out[44]=

For the same reason, the metric with one upper and one lower index is just the identity matrix:

In[45]:=

TList["Schwarzschild", {1, -1}]

Schwarzschild:

Out[45]=

$$g_{t}^{t} = g_{r}^{r} = g_{\theta}^{\theta} = g_{\phi}^{\phi} = 1$$

As explained above, if the modules TShow or TList are called without any arguments, the tensor is displayed in its default index configuration, which is the one first used to define the tensor. So the 4velocity has one upper index by default, and the stress tensor has two upper indices by default, because that is how we initially defined them. However, the default indices can be changed using the module TChangeDefaultIndices:

Out[46]=

? TChangeDefaultIndices

Symbol

TChangeDefaultIndices[ID, indices] changes the default index configuration of the tensor object ID to indices.

indices is a list of the form {±1, ±1, ...}, where +1 corresponds to an upper index and -1 corresponds to a lower index.

~

For example, let us change the default indices of the perfect fluid stress tensor to two lower indices:

In[47]:= TChangeDefaultIndices["PerfectFluid", {-1, -1}];

Now, when we display the tensor using **TShow** without any arguments, this is the index configuration that will be used:

In[48]:=

TShow["PerfectFluid"]

Out[48]=

PerfectFluid:
$$T_{\mu\nu}(t, x, y, z) = \begin{pmatrix} \rho & 0 & 0 & 0 \\ 0 & \rho & 0 & 0 \\ 0 & 0 & \rho & 0 \\ 0 & 0 & 0 & \rho \end{pmatrix}$$

Coordinate transformations

The components of any tensor may be transformed from one coordinate system x^{μ} to another coordinate system x^{μ} using the following prescription:

- For every lower index μ , add a factor of $\partial \mathbf{x}^{\mu}/\partial \mathbf{x}^{\mu'}$ (i.e. the derivative of the old coordinates with respect to the new, or the **Jacobian**).
- For every upper index μ , add a factor of $\partial \mathbf{x}^{\mu'}/\partial \mathbf{x}^{\mu}$ (i.e. the derivative of the new coordinates with respect to the old, or the inverse of the Jacobian).

For example, given a tensor with components $T_{\alpha\beta}$ in a coordinate system x^{μ} , we can transform to components $T_{\alpha'\beta'}$ in another coordinate system $x^{\mu'}$ as follows:

$$\mathsf{T}_{\alpha'\beta'}\left(\mathsf{x}^{\mu'}\right) = \frac{\partial \mathsf{x}^{\alpha}}{\partial \mathsf{x}^{\alpha'}} \frac{\partial \mathsf{x}^{\beta}}{\partial \mathsf{x}^{\beta'}} \mathsf{T}_{\alpha\beta} \left(\mathsf{x}^{\mu}\right).$$

For a general rank (p, q) tensor with p upper indices $\alpha_1, ..., \alpha_p$ and q lower indices $\beta_1, ..., \beta_q$, the transformation takes the form

$$T_{\beta_{1}^{\prime}\cdots\beta_{q}^{\prime}}^{\alpha_{1}^{\prime}\cdots\alpha_{p}^{\prime}}\left(x^{\mu^{\prime}}\right) = \left(\frac{\partial x^{\alpha_{1}^{\prime}}}{\partial x^{\alpha_{1}}}\cdots\frac{\partial x^{\alpha_{p}^{\prime}}}{\partial x^{\alpha_{p}}}\right) \left(\frac{\partial x^{\beta_{1}}}{\partial x^{\beta_{1}^{\prime}}}\cdots\frac{\partial x^{\beta_{q}}}{\partial x^{\beta_{q}^{\prime}}}\right) T_{\beta_{1}\cdots\beta_{q}}^{\alpha_{1}\cdots\alpha_{p}}\left(x^{\mu}\right).$$

As a mnemonic for this formula, recall that two indices may only be contracted if one of them is an upper index and the other is a lower index. If an index is in the denominator of a derivative, then its role is reversed (upper \leftrightarrow lower). Thus the old (non-primed) and new (primed) indices can only be in places that allow properly contracting the Jacobian or inverse Jacobian with the tensor. For example, α_1 is an upper index in T and therefore must be contracted with a lower index. Thus, ∂x^{α_1} must be in the denomi nator, to lower its index and allow it to be contracted with the tensor.

As we saw above, OGRe automatically knows how to raise or lower indices as needed using the appropriate metric. Similarly, any operation that requires transforming to another coordinate system will preform the transformation automatically behind the scenes. However, for this to happen, OGRe needs to know the appropriate transformation rules. These are defined between the tensor objects representing the coordinates, which were generated using the module TNewCoordinates. The rules for transforming from a source coordinate system to a target coordinate system are stored within the tensor object representing the source. This is done using the module TAddCoordTransformation:

? TAddCoordTransformation In[49]:= TAddCoordTransformation[sourceID, targetID, rules] adds a transformation from the coordinate system sourceID to the coordinate system targetID. Out[49]= The argument **rules** must be a list of transformation rules. For example, $\{x \to r \operatorname{Sin}[\theta] \operatorname{Cos}[\phi], y \to r \operatorname{Sin}[\theta] \}$ $Sin[\phi]$, $z \to r Cos[\theta]$ is a transformation from Cartesian to spherical coordinates.

Let us add the rules to transform from Cartesian to spherical coordinates:

TAddCoordTransformation["Cartesian", "Spherical", In[50]:= $\{x \rightarrow r \sin[\theta] \cos[\phi], y \rightarrow r \sin[\theta] \sin[\phi], z \rightarrow r \cos[\theta]\}\}$;

These will be stored in the data of the object "Cartesian". Note that we did not have to input a rule for t, since in this case, it stays the same. Conversely, let us add the rules to transform from spherical to Cartesian coordinates:

TAddCoordTransformation ["Spherical", "Cartesian", $\left\{r \rightarrow \sqrt{x^2 + y^2 + z^2}, \; \theta \rightarrow \text{ArcCos}\left[\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right], \; \phi \rightarrow \text{ArcTan}\left[x, \; y\right]\right\}\right];$

These will be stored in the data of the object "Spherical". Now OGRe knows how to convert back and forth between these two coordinate systems - and this will happen automatically whenever required.

In[52]:=

Out[52]=

As in the case of raising and lowering indices, displaying a tensor in a different coordinate system is a simple matter of calling the modules **TShow** or **TList** with an additional argument specifying the coordinate system to use. For example, let us show the Minkowski metric in spherical coordinates:

TShow["Minkowski", "Spherical"]

Minkowski: $\eta_{\mu\nu}(t, r, \theta, \phi) = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & r^2 & 0 \\ 0 & 0 & 0 & r^2 \text{Sin}[\theta]^2 \end{pmatrix}$

We can also ask to see a tensor in a specific index configuration **and** a specific coordinate system:

TShow["PerfectFluid", {1, 1}, "Spherical"]

Out[53]=

PerfectFluid: $T^{\mu\nu}(t, r, \theta, \phi) = \begin{pmatrix} \rho & 0 & 0 & 0 \\ 0 & \rho & 0 & 0 \\ 0 & 0 & \frac{\rho}{r^2} & 0 \\ 0 & 0 & 0 & \frac{\rho \operatorname{Csc}[\theta]^2}{r^2} \end{pmatrix}$

The module **TList** works in exactly the same way, for example:

TList["Kretschmann", "Cartesian"]

Kretschmann: $K = \frac{48 M^2}{(x^2+y^2+z^2)^3}$

Just as with default indices, every tensor has a **default coordinate system**, which is, initially, the one we used to create it. We can change it using the module **TChangeDefaultCoords**, and then whenever we display the tensor, it will be displayed in that coordinate system if no other coordinate system is specified:

? TChangeDefaultCoords In[55]:= Symbol TChangeDefaultCoords[tensorID, coordinatesID] changes the default coordinate system of the tensor Out[55]= object tensorID to coordinatesID.

For example, let's change the default coordinates of the perfect fluid stress tensor to spherical coordinates:

In[56]:= TChangeDefaultCoords["PerfectFluid", "Spherical"];

Now, when we display the tensor using TList without any arguments (or with just indices), this is the coordinate system that will be used:

TList["PerfectFluid"] In[57]:= PerfectFluid: $T_{tt} = \rho$ $T_{rr} = p$ Out[57]= $T_{\theta\theta} = p r^2$ $\mathsf{T}_{\phi\phi} = p \, r^2 \, \mathsf{Sin}[\theta]^2$

Setting simplification assumptions

Often, coordinate transformations are only invertible for a specific range of coordinates. For example, let us define a new scalar in Minkowski space, which is equal to the spatial distance from the origin:

 $TShow@TNewTensor\Big["SpatialDistance", "Minkowski", "Cartesian", {}, \Big\{\sqrt{x^2+y^2+z^2}\Big\}, "d"\Big]$ In[58]:= SpatialDistance: d $(t, x, y, z) = \sqrt{x^2 + y^2 + z^2}$ Out[58]=

When we convert this scalar to spherical coordinates, we expect to get r, but instead we get the absolute value of r:

TShow["SpatialDistance", "Spherical"] In[59]:= SpatialDistance: d $(t, r, \theta, \phi) = Abs[r]$ Out[59]=

As usual in Mathematica, such issues can be easily fixed by using FullSimplify with the correct assump tions. Most OGRe modules run their output through FullSimplify automatically. By default, OGRe uses the simplification assumption that all variables (coordinates, parameters, etc.) are real. Therefore, Mathematica knows to simplify $\sqrt{r^2}$ to |r|. However, Mathematica doesn't automatically know that r is non-negative.

The user may specify which assumptions to pass to FullSimplify using the module TSimplifyAssumptions:

Note that these assumptions will be globally applied to all tensor calculations, which is usually the desired behavior, since for example the assumption $r \ge 0$ should apply to all tensors that use spherical coordinates. Let us set this assumption now:

```
TSimplifyAssumptions [r \ge 0]
 In[61]:=
               \langle | AssumeReal \rightarrow True, User \rightarrow \{r \geq 0\} | \rangle
Out[61]=
```

In fact, it is good practice to set any assumptions regarding the coordinates as soon as they are **defined**, so we should have set this assumption already when we defined the spherical coordinates in the beginning of this documentation. From now on, this assumption will automatically be used by modules that perform any kind of calculations on tensors. However, if we now try to show the scalar again using **TShow**, we still get the same (non-simplified) result:

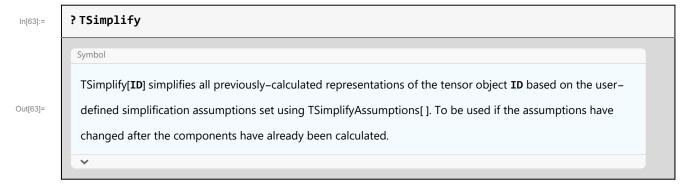

```
TShow["SpatialDistance", "Spherical"]
                      SpatialDistance: d (t, r, \theta, \phi) = Abs[r]
```

In[62]:=

Out[62]=

The reason is that when OGRe calculates the components of a tensor in a particular representation, it calculates them once and for all, and then saves them in the object's data to be reused later. This is done to improve performance, so that the components don't have to be recalculated every time they are needed. In this case, since we already calculated the spatial distance in spherical coordinates when we showed it above - **before** we set the new simplification assumptions - that value has been saved, and will not be recalculated automatically, even though we now have new assumptions.

However, we can force the simplification of the stored components with the new assumptions using the module TSimplify:

Now we get the expected result:

TShow[TSimplify["SpatialDistance"], "Spherical"]

Out[64]=

SpatialDistance:
$$d(t, r, \theta, \phi) = r$$

Here, again, note that TSimplify returns the ID of the tensor it simplifies, so we can compose it with TShow if we want to show that same tensor. However, since we are now using TShow with a second argument, we put TSimplify["SpatialDistance"] as the first argument, instead of composing it directly with @.

Finally, we note that if you are using non-real variables, you can disable the assumption that all variables are real using TSimplifyAssumptions[!Reals]. If you later want to turn it back on, use TSimplifyAssumptions[Reals]. The value of the key "AssumeReal" in the output of **TSimplifyAssumptions** indicates whether this assumption is turned on.

Importing and exporting tensors

In a single Mathematica session, one can spend considerable time and effort defining tensors and doing various operations on them. However, as the tensors are only stored in memory, once the session is over and the kernel is stopped, all that information will be lost. Due to the non-linear nature of Mathematica notebooks, even if you saved the entire notebook, it can be hard or even impossible to retrace your steps and get the exact same tensors again from the information in the notebook.

Instead of defining all the tensors from scratch, OGRe allows the user to export tensors and then import them in another session to continue working with them later. The tensors are stored internally as an Association, and exporting a tensor essentially amounts to outputting the corresponding Association. Warning: Do not change the exported data manually, as that might break the class invariants and cause errors after importing it back!

To export a single tensor, use the **TExport** module:

In[65]:=	? TExport	
	Symbol	
Out[65]=	TExport[ID] exports the raw tensor data for the tensor object ID as an Association.	
	~	

For example, here is how the 4-velocity is stored internally:

```
TExport["4-Velocity"]
 In[66]:=
                      \left\langle \left| \text{ 4-Velocity} \rightarrow \left\langle \left| \text{ Components} \rightarrow \left\langle \left| \left\{ \left\{ 1 \right\} \text{, Cartesian} \right\} \right. \right. \right. \right. \left. \left. \left. \left( \frac{1}{\sqrt{1-v^2}} \right), \frac{v}{\sqrt{1-v^2}} \right] \right\rangle \right\rangle \right\rangle \right\rangle 
Out[66]=
                                    \{\{-1\}, Cartesian\} \rightarrow \left\{-\frac{1}{\sqrt{1-v^2}}, \frac{v}{\sqrt{1-v^2}}, \emptyset, 0\right\} \mid \rangle
                               \label{eq:DefaultCoords} \textbf{DefaultIndices} \rightarrow \{\textbf{1}\} \textbf{,} \ \textbf{Metric} \rightarrow \textbf{Minkowski},
                                Role 
ightarrow Tensor, Symbol 
ightarrow u, OGReVersion 
ightarrow v1.1 (April 15, 2021) \Big| \left. 
ight
angle \Big| \left. 
ight
angle
```

This is a nested Association. The upper level has just one key: "4-Velocity", which is the ID of the tensor. Its value is another **Association**, which has the following keys:

- "Components": An Association containing the components of the tensor in different representations, each with a specific index configuration and coordinate system. The components are only generated when a particular combination of indices and coordinates is requested for the first time, so for example, here the components with both an upper and a lower index in Minkowski coordinates have been stored, but no components in spherical coordinates, since we have not tried to access them so far.
- "DefaultCoords": The default coordinate system to use when displaying the tensor.
- "DefaultIndices": The default index configuration to use when displaying the tensor.
- "Metric": The unique ID of the metric that will be used to raise and lower the tensor's indices. Note that this is only a reference, so a tensor object with this ID must exist. If a tensor is exported, its metric must be exported separately as well for raising and lowering of indices to work.
- "Role": The role of the tensor, which depends on the module that created it. Will be "Coordinates" if the tensor was created using TNewCoordinates, "Metric" if the tensor was created using TNewMetric, or "Tensor" if the tensor was created using TNewTensor. Other modules that we will discuss below, such as TCalc, TChristoffel, and TRiemannTensor, have corresponding roles as well. Additional roles are only used internally by OGRe, such as "Temporary" for a temporary tensor

created as an intermediate step in a calculation.

- "Symbol": The symbol used to represent the tensor when displaying it.
- "OGReVersion": The version of the package used to create the tensor. This will be used in future versions to ensure backwards compatibility. Note that this key is not stored internally, it is added by TExport.

Other keys also exist in special cases. For example, for tensor objects representing coordinate systems, the keys "CoordTransformations" and "Jacobians" are used to store the details of coordinate transformations defined using TAddCoordTransformation, as can be seen by exporting "Cartesian":

```
TExport["Cartesian"]
\langle | Cartesian \rightarrow \rangle
     \left\langle \, \left| \, \mathsf{Components} \, \rightarrow \, \left\langle \, \right| \, \left\{ \, \{1\} \, \text{, Cartesian} \, \right\} \, \rightarrow \, \left\{ \, \text{t, x, y, z} \, \right| \, \right\rangle \, \text{, DefaultCoords} \, \rightarrow \, \mathsf{Cartesian} \, , \right. \right.
      DefaultIndices \rightarrow {1}, Role \rightarrow Coordinates, Symbol \rightarrow x, CoordTransformations \rightarrow
         \langle | \mathsf{Spherical} \to \{ \mathsf{x} \to \mathsf{r} \, \mathsf{Cos} \, [\phi] \, \mathsf{Sin} [\theta] \, , \, \mathsf{y} \to \mathsf{r} \, \mathsf{Sin} [\theta] \, \mathsf{Sin} [\phi] \, , \, \mathsf{z} \to \mathsf{r} \, \mathsf{Cos} [\theta] \, \} \, \Big| \rangle \, ,
      Jacobians \rightarrow \langle | Spherical \rightarrow \langle | Jacobian \rightarrow \rangle
                   \{\{1, 0, 0, 0\}, \{0, \cos[\phi] \sin[\theta], r\cos[\theta] \cos[\phi], -r\sin[\theta] \sin[\phi]\}, \{0, \cos[\phi], -r\sin[\theta]\}\}
                       Sin[\theta] Sin[\phi], r Cos[\theta] Sin[\phi], r Cos[\phi] Sin[\theta]}, \{0, Cos[\theta], -r Sin[\theta], 0\}},
                InverseJacobian \rightarrow \{ {1, 0, 0, 0}, {0, Cos}[\phi] Sin[\theta], Sin[\theta] Sin[\phi], Cos[\theta]},
                     \left\{0, \frac{\cos[\theta]\cos[\phi]}{r}, \frac{\cos[\theta]\sin[\phi]}{r}, -\frac{\sin[\theta]}{r}\right\}
                    \left\{\emptyset, -\frac{\mathsf{Csc}\left[\theta\right]\,\mathsf{Sin}\left[\phi\right]}{\mathsf{r}}, \frac{\mathsf{Cos}\left[\phi\right]\,\mathsf{Csc}\left[\theta\right]}{\mathsf{r}}, \emptyset\right\}\right\}, ChristoffelJacobian \to
                   \{\emptyset, \emptyset, \mathsf{Cos}[\theta] \mathsf{Cos}[\phi], -\mathsf{Sin}[\theta] \mathsf{Sin}[\phi]\}, \{\emptyset, \mathsf{Cos}[\theta] \mathsf{Cos}[\phi], -\mathsf{rCos}[\phi] \mathsf{Sin}[\theta]\}
                         -r\cos[\theta]\sin[\phi], \{0, -\sin[\theta]\sin[\phi], -r\cos[\theta]\sin[\phi], -r\cos[\phi]\sin[\theta]\},
                     \{\{0, 0, 0, 0\}, \{0, 0, \cos[\theta] \sin[\phi], \cos[\phi] \sin[\theta]\},\
                       \{0, \cos[\theta] \sin[\phi], -r\sin[\theta] \sin[\phi], r\cos[\theta] \cos[\phi]\},
                       \{0, \cos[\phi] \sin[\theta], r\cos[\theta] \cos[\phi], -r\sin[\theta] \sin[\phi]\}\}, \{\{0, 0, 0, 0\}, \{0, 0, 0\}\}
                       \{0,0,-{\sf Sin}[\theta],0\},\{0,-{\sf Sin}[\theta],-{\sf rCos}[\theta],0\},\{0,0,0,0\}\}\}\left|\right\rangle\left|\right\rangle
      OGReVersion \rightarrow v1.1 (April 15, 2021) |\rangle
```

The output of TExport is a raw Association, and is not intended to be read by humans. If you wish to display the information encoded in the object in human-readable form, use TInfo:

In[67]:=

Out[67]=

In[68]:=

Out[68]=

? TInfo

Symbol

TInfo[ID] displays information about the tensor object ID, including its symbol, role, associated metric, and default coordinates and indices, in human-readable form.

If ID represents a coordinate system, displays a list of all tensors using it as their default coordinate system.

If ID represents a metric, displays a list of all tensors using it as their associated metric.

TInfo will also tell you which other tensor objects use this tensor as their metric or default coordinate system, if applicable. For example:

In[69]:=

TInfo["Cartesian"]

ID: Cartesian

Symbol: x

Role: Coordinates Default Indices: {1}

Default Coordinates For: Minkowski, 4-Velocity, SpatialDistance

In[70]:=

TInfo["Minkowski"]

ID: Minkowski

Symbol: η

Role: Metric

Default Coordinates: Cartesian

Default Indices: $\{-1, -1\}$

Tensors Using This Metric: PerfectFluid, 4-Velocity, SpatialDistance

In[71]:=

TInfo["PerfectFluid"]

ID: PerfectFluid

Symbol: T

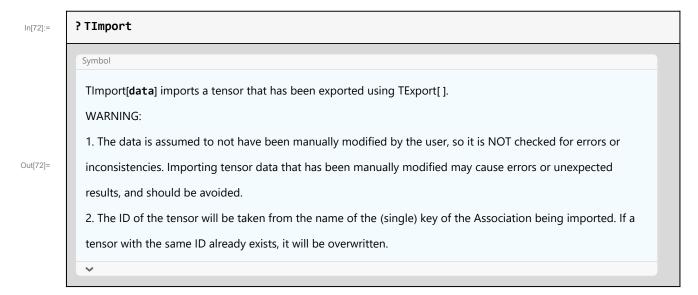

Role: Tensor

Metric: Minkowski

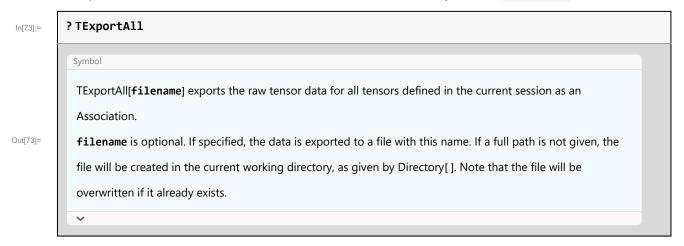

Default Coordinates: Spherical

Default Indices: $\{-1, -1\}$

To import a tensor back after it has been exported, use the **TImport** module:

To export **all** of the tensors defined in the current session, we may use the **TExportAll** module:

The output will be an Association as above, where the keys are the names of all the tensors defined so far in the current session, and the value of each key is the data of that tensor. We will not show the complete output here, since it is very long, but let us just demonstrate that the keys of the Association are all of the tensors we defined so far in this session:

```
Keys[TExportAll[]]
In[74]:=
         {Options, Cartesian, Spherical, Minkowski, Schwarzschild,
Out[74]=
          Kretschmann, PerfectFluid, 4-Velocity, SpatialDistance}
```

Tip: To quickly display information about all the tensors defined so far, map the keys of **TExportAll**[] into TInfo using TInfo/@Keys@TExportAll[].

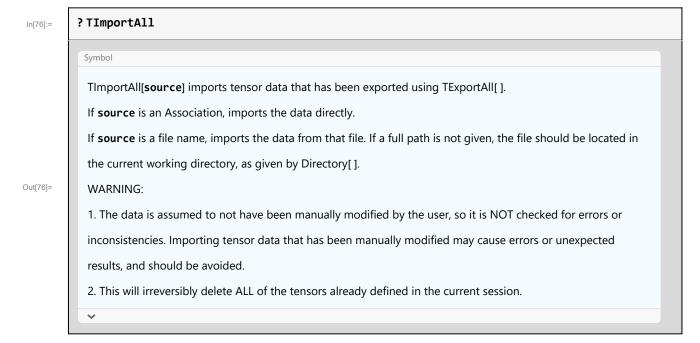

TExportAll exports not only the tensors, but also a special key called Options, which contains the current version of the package (for compatibility purposes, in case the storage format changes in future versions) and any options set by the user during the session. Note that keys associated with tensor

objects, such as "Cartesian", "Spherical", and so on, are always strings, but Options is not a string; this is to ensure it doesn't get accidentally interpreted as a tensor object.

Currently, the options exported by TExportAll are the index letters (e.g. if you changed them to English letters) and the simplification assumptions. We can see this by reading the value of the Options key:

```
TExportAll[][Options]
In[75]:=
             \langle | OGReVersion \rightarrow v1.1 (April 15, 2021), IndexLetters \rightarrow \muνρσκλαβγδεζεθιξπτφχψω,
Out[75]=
              SimplifyAssumptions \rightarrow \langle | AssumeReal \rightarrow True, User \rightarrow \{r \ge 0\} | \rangle | \rangle
```

The output of TExportAll can be saved in a Mathematica notebook, and imported using the module TImportAll:

Note that TImportAll will delete any tensors already defined in the current session, whether or not they have the same ID as an imported tensor. To keep them, first export them into an Association, Join it with the Association you wish the import, and then use TImportAll on the result - or, alternatively, import the tensors one by one using TImport.

If a file name is given to TExportAll, the output will be saved to that file. If only the name of the file is given, and not a full path - e.g. TExportA11 ["OGReTensors.m"] - then the file will be saved in the current working directory, as given by Directory[]. To change the working directory, use SetDirectory[] before exporting the file. To import from the file, pass the file name to TImportAll, e.g. TImportAll["OGReTensors.m"].

Note that if for some reason you would like to delete all the tensors defined so far in the current session, you can simply import an empty Association as follows: TImportAll[<||>]. Be careful, as this action is irreversible!

Finally, sometimes you may want to extract the components of a tensor in a specific representation as a List so you can use them outside of this package, as regular Mathematica expressions rather than tensor objects. This is done using TGetComponents:

? TGetComponents In[77]:= Symbol

> TGetComponents[ID, indices, coordinatesID] extracts the components of the tensor object ID with the index configuration indices and in the coordinate system coordinatesID as a regular Mathematica List.

indices should be a list of the form {±1, ±1, ...}, where +1 corresponds to an upper index and -1 corresponds to a lower index.

The index configuration and/or coordinate system cannot be omitted; there are no default values. This is to ensure that the user always knows which representation is being extracted.

For example:

Out[77]=

In[78]:=

Out[78]=

In[79]:=

InverseSchwarzschild = TGetComponents["Schwarzschild", {1, 1}, "Spherical"]

 $\left\{\left\{\frac{r}{2M-r}, 0, 0, 0\right\}, \left\{0, 1-\frac{2M}{r}, 0, 0\right\}, \left\{0, 0, \frac{1}{r^2}, 0\right\}, \left\{0, 0, 0, \frac{\csc[\theta]^2}{r^2}\right\}\right\}$

We can now treat InverseSchwarzschild as any other List in Mathematica - for example, extract the element at a particular position:

InverseSchwarzschild[[1, 1]]

r Out[79]= 2M-r

Calculations with tensors

The TCalc module

Now that we have all the bookkeeping of tensors out of the way, we can finally discuss how to use those tensors in calculations. In OGRe, all tensor calculations are performed using the TCalc module: In[80]:=

Out[80]=

? TCalc

Symbol

TCalc[LHSTensorID[LHSIndices], RHSExpression, symbol] calculates a tensor formula.

RHSExpression may include any number of tensors in the format ID[indices], where ID is a tensor object and indices is a string representing the order of indices, along with any combination of the following operations:

- Addition: For example, "A"[" μv "] + "B"[" μv "].
- Contraction: For example, "A"[" $\mu\lambda$ "] . "B"[" $\lambda\nu$ "].
- Multiplication by scalar: For example, $2 * "A"["\mu\nu"]$.

LHSTensorID specifies the ID of the tensor object in which to store the result. If omitted, the ID "Result" will be used.

LHSIndices specifies the order of indices of the resulting tensor. The indices must be a permutation of the free indices of RHSExpression. If omitted, the indices will be in the same order as they appear in RHSExpression. If LHSTensorID is omitted, then LHSIndices must be omitted as well.

symbol specifies the symbol to use for the result. If omitted, the placeholder symbol □ will be used.

Any use of TCalc should be thought of as invoking a tensor equation of the form

$$L_{\beta_1 \dots \beta_q}^{\alpha_1 \dots \alpha_p} = R_{\beta_1 \dots \beta_q}^{\alpha_1 \dots \alpha_p}$$
,

where both the left-hand side and the right-hand side are tensors of the same rank and with the same **free indices** (that is, indices that are not being contracted). $L_{\beta_1\cdots\beta_n}^{\alpha_1\cdots\alpha_p}$ is the tensor that will be used to store the result, while $R_{\beta_1 \cdots \beta_n}^{\alpha_1 \cdots \alpha_p}$ is (the final result of) a general tensor calculation which contains any combination of addition, multiplication by scalar, trace, contraction, partial derivative, and covariant derivative. Let us now go over these operations one by one, and give some examples.

Addition of tensors

Addition of tensors in OGRe is represented by a sum of the form "ID1"["indices1"] + "ID2" ["indices2"], where "ID1" and "ID2" are the IDs of the tensor objects to be added, and "indices1" and "indices2" are the index specifications for each tensor, given as a string of letters. Note that you do **not** specify the position (upper or lower) of the indices. Furthermore, just like in any tensor equation, the index letters themselves have no meaning; they are just placeholders. Therefore, "αβγ", "abc", and "ABC" are all completely equivalent. The only requirement is that the indices are consistent; in the case of addition, this means that both tensors being added must have the same indices up to permutation.

The following constraints apply to addition of tensors:

- You may not add a tensor representing a coordinate system to any other tensor, since coordinates do not transform like tensors.
- You may not add two tensors associated with different metrics, since their sum would have undefined transformation properties.
- You may not add two tensors with different ranks, since that is not a well-defined operation.
- As stated above, both tensors must have the same indices up to permutation. $A^{\mu\nu} + B^{\mu\nu}$ and $A^{\mu\nu} + B^{\nu\mu}$ are both okay, but $A^{\mu\nu} + B^{\alpha\beta}$ doesn't make sense, as it has more free indices than the rank of the result.

As an example, let us add the Minkowski metric η_{uv} and the perfect fluid stress tensor T_{uv} :

TShow@TCalc["Minkowski"[" $\mu\nu$ "] + "PerfectFluid"[" $\mu\nu$ "]] In[81]:= Result: $\square_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1+\rho & 0 & 0 & 0 \\ 0 & 1+\rho & 0 & 0 \\ 0 & 0 & 1+\rho & 0 \\ 0 & 0 & 0 & 1+\rho \end{pmatrix}$

Notice that the result was stored in a tensor with ID "Result", and has no symbol. We can add a symbol to use as an additional argument:

TShow@TCalc["Minkowski"[" $\mu\nu$ "] + "PerfectFluid"[" $\mu\nu$ "], "S"] In[82]:= Result: $S_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1+\rho & 0 & 0 & 0 \\ 0 & 1+\rho & 0 & 0 \\ 0 & 0 & 1+\rho & 0 \\ 0 & 0 & 0 & 1+\rho \end{pmatrix}$

With this symbol, the tensor equation we are calculating becomes:

$$S_{\mu\nu} = \eta_{\mu\nu} + T_{\mu\nu}.$$

We can also use a different ID for the result by giving it as the first argument, with or without a symbol:

Out[81]=

Out[82]=

Out[83]=

TShow@TCalc["SumResult", "Minkowski"[" $\mu\nu$ "] + "PerfectFluid"[" $\mu\nu$ "], "S"] TDelete["SumResult"]

SumResult: $S_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1+\rho & 0 & 0 & 0 \\ 0 & 1+\rho & 0 & 0 \\ 0 & 0 & 1+\rho & 0 \\ 0 & 0 & 0 & 1+\rho \end{pmatrix}$

(We deleted the result to avoid cluttering the tensor data with unused objects.) In the following examples, we will not specify a symbol, to keep the code cleaner.

Sometimes it is also helpful to specify indices for the result. To give an example, let us define the following non-symmetric tensor:

In[85]:=

TShow@TNewTensor["NonSymmetric", "Minkowski", "Cartesian", {-1, -1}, {{0,0,0,1}, {0,0,0,0}, {0,0,0,0}, {0,0,0,0}}, "N"]

Out[85]=

If we add it to the Minkowski metric, we get:

$$\square_{\mu\nu} = \eta_{\mu\nu} + \mathbf{N}_{\mu\nu},$$

In[86]:=

 ${\sf TShow@TCalc["Minkowski"["}\mu\nu"] + "NonSymmetric"["}\mu\nu"]]$

Out[86]=

Result:
$$\square_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

However, if we flip its index string from " $\mu\nu$ " to " $\nu\mu$ ", then we instead get:

$$\square_{\mu\nu} = \eta_{\mu\nu} + \mathbf{N}_{\nu\mu},$$

TShow@TCalc["Minkowski"[" $\mu\nu$ "] + "NonSymmetric"[" $\nu\mu$ "]]

Result: $\square_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}$

Out[87]=

Since the order of indices now matters, we can also define an index string for the left-hand side, to indicate the order of indices we want in the result. If that string is also " $\nu\mu$ ", then we get back to the original result:

$$\square_{\nu\mu} = \eta_{\mu\nu} + \mathbf{N}_{\nu\mu},$$

In[88]:=

TShow@TCalc["Result"[" $\nu\mu$ "], "Minkowski"[" $\mu\nu$ "] + "NonSymmetric"[" $\nu\mu$ "]]

Result: $\square_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Out[88]=

We see that explicitly specifying the indices in TCalc allows it to have a 1-to-1 correspondence with any tensor equation. Importantly, note that there is no difference between "NonSymmetric" [" $\mu\nu$ "] and "NonSymmetric" [" $\nu\mu$ "] on its own, as the index labels themselves are meaningless unless there is some context in which they obtain meaning - as is always the case for tensor expressions. However, there is a big difference between, for example, "Minkowski" [" $\mu\nu$ "] + "NonSymmetric" [" $\mu\nu$ "] and "Minkowski" [" $\mu\nu$ "] + "NonSymmetric" [" $\nu\mu$ "], as the indices have a different order, and thus the two expressions refer to adding different components.

Of course, any number of tensors can be added, not just two - and the same tensor can be added with different index configurations. For example, we can calculate:

$$\square_{\mu\nu} = \eta_{\mu\nu} + \mathsf{T}_{\mu\nu} + \mathsf{N}_{\mu\nu} + \mathsf{N}_{\nu\mu},$$

In[89]:=

TShow@TCalc["Minkowski"[" $\mu\nu$ "] +

"PerfectFluid"[" $\mu\nu$ "] + "NonSymmetric"[" $\mu\nu$ "] + "NonSymmetric"[" $\nu\mu$ "]]

Result: $\square_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -1+\rho & 0 & 0 & 1\\ 0 & 1+\rho & 0 & 0\\ 0 & 0 & 1+\rho & 0\\ 1 & 0 & 0 & 1+\rho \end{pmatrix}$

Out[89]=

Multiplication of tensor by scalar

Multiplication of tensor by scalar in OGRe is represented by a product of the form scalar * "ID"["indices"], where "ID" is the ID of the tensor object to be multiplied, "indices" is an index specification as for addition, and scalar is the scalar to multiply by. Note that scalar should be a normal Mathematica symbol, such as a number or a variable, and not a tensor object of rank 0. To multiply a tensor by a tensor of rank 0, use contraction instead, as detailed in the next section.

As an example, let us multiply the Minkowski metric $\eta_{\mu\nu}$ by 2. The tensor equation we will be calculating is:

$$\square_{\mu\nu}=2\,\eta_{\mu\nu},$$

and the OGRe expression to calculate it (and show the result) is:

TShow@TCalc[2"Minkowski"["
$$\mu\nu$$
"]]

Result:
$$\square_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix}$$

While in this example the indices seem redundant, they are necessary because in most non-trivial situations we would like to combine multiplication with other operations, such as addition or contraction, in which the order of indices matters. For example, consider:

$$\square_{\mu\nu} = 2 t\eta_{\mu\nu} - 3 xT_{\mu\nu} + 4 yN_{\mu\nu} - 5 zN_{\nu\mu}$$

Taking traces and contracting tensors: theoretical review

The most complicated tensor operation is **contraction**, a generalization of the vector inner product. This is done by summing over one or more disjoint pairs of indices, with each pair containing exactly one upper index and one lower index. Raising and lowering indices is one example of contraction: the metric (or its inverse) is contracted with a tensor. Coordinate transformations are another example, where we contract the Jacobian (or its inverse) with a tensor.

The simplest example of contraction is the **vector inner product**, which is defined as the contraction of a vector (one upper index) with a covector (one lower index):

$$\mathbf{V}^{\mu} \mathbf{W}_{\mu} = \mathbf{g}_{\mu \nu} \mathbf{V}^{\mu} \mathbf{W}^{\nu} = \mathbf{g} (\mathbf{V}, \mathbf{W})$$
.

The middle part of this equality comes from the fact that, as explained above, when we lower an index on w^{ν} , we use the metric:

$$\mathbf{w}_{\mu} = \mathbf{g}_{\mu\nu} \mathbf{w}^{\nu}$$
.

This, in turn, justifies the notation q(v, w) on the right-hand side, as this is, in fact, an inner product of two vectors using the metric q (in index-free notation).

Contraction of indices in higher-rank tensors is simply a generalization of the inner product, for example:

$$\mathbf{A}^{\mu\alpha} \mathbf{B}_{\alpha\nu} = \mathbf{g}_{\alpha\beta} \mathbf{A}^{\mu\alpha} \mathbf{B}^{\beta}_{\nu}$$
.

We can also contract more than one index:

$$A^{\mu\nu} B_{\mu\nu} = g_{\mu\alpha} g_{\nu\beta} A^{\mu\nu} B^{\alpha\beta}$$
.

This simply amount to the fact that lowering both indices of $B^{\alpha\beta}$ involves contracting each index with the metric. We can even contract two indices of the same tensor:

$$\mathbf{A}^{\mu}_{\mu} = \mathbf{g}_{\mu\nu} \mathbf{A}^{\mu\nu}$$
.

This is also called taking the trace. Furthermore, it is also possible to contract pairs of indices from more than two tensors at the same time:

$$A^{\mu\nu} B_{\nu\rho} C^{\rho\sigma} = g_{\nu\alpha} g_{\rho\beta} A^{\mu\nu} B^{\alpha\beta} C^{\rho\sigma}$$
.

However, such operations can always be broken down into individual contractions of pairs of tensors. For example, in this case, one could first contract $B_{\nu\rho}$ with $C^{\rho\sigma}$ and then contract the result with $A^{\mu\nu}$ which is indeed how this kind of contraction will be performed in OGRe in practice:

$$\mathbf{A}^{\mu\nu} \mathbf{B}_{\nu\rho} \mathbf{C}^{\rho\sigma} = \mathbf{A}^{\mu\nu} (\mathbf{B}_{\nu\rho} \mathbf{C}^{\rho\sigma})$$
.

In a contraction, there are two types of indices: contracted indices, which are summed upon, and free indices, which are not summed upon. The rank of the tensor that results from the contraction is the number of free indices. So for example, in the expression $A^{\mu\alpha}$ $B_{\alpha\nu}$ we have one contracted index, α , and two free indices, μ and ν . Therefore, the resulting tensor is of rank two: $\mathsf{T}^{\mu}_{\nu} = \mathsf{A}^{\mu\alpha} \mathsf{B}_{\alpha\nu}$.

Taking traces and contracting tensors: OGRe syntax

Contraction of tensors in OGRe is represented by an expression of the form "ID1"["indices1"]. "ID2"["indices2"], where "ID1" and "ID2" are the IDs of the tensor objects to be contracted, and "indices1" and "indices2" are the index strings for each tensor. Any matching indices in both index strings will be contracted. This means that, for example, \mathbf{v}^{μ} \mathbf{w}_{μ} is calculated using "v" [" μ "].

"w"[" μ "] and $A^{\mu\nu}$ $B_{\nu\rho}$ $C^{\rho\sigma}$ is calculated using "A"[" $\mu\nu$ "] . "B"[" $\nu\rho$ "] . "C"[" $\rho\sigma$ "]. Note that the user doesn't need to worry about the contracted indices being one upper and one lower, which is a common source of errors when contracting tensors by hand; the order of the indices, and whether the same index repeats twice, is all that matters.

As a first example, let us create the stress-energy tensor for a perfect fluid with a 4-velocity u^{μ} . This is defined as follows:

$$T^{\mu\nu} = (\rho + p) u^{\mu} u^{\nu} + pg^{\mu\nu}.$$

Even though this does not involve any contractions, it still counts as a "trivial" contraction, since two tensors (the 4-velocities) are juxtaposed next to each other to create another tensor. This is also known as an **outer product**. Therefore, it uses the same dot product syntax as any other contraction, except that there are no matching indices. Note that this expression involves not just contraction (in the first term), but also multiplication by scalar (in both terms), and addition of the two terms together. Again, OGRe takes care of everything behind the scene, so this just works:

TShow@TCalc["PerfectFluid", In[92]:= $(\rho + p)$ "4-Velocity"[" μ "]."4-Velocity"[" ν "] + p "Minkowski"[" $\mu\nu$ "], "T"] PerfectFluid: $T_{\mu\nu}(t, x, y, z) = \begin{bmatrix} \frac{1}{1-v^2} & \frac{1}{-1+v^2} & 0 & 0 \\ \frac{v(p+\rho)}{-1+v^2} & \frac{p+v^2\rho}{1-v^2} & 0 & 0 \\ 0 & 0 & p & 0 \\ 0 & 0 & 0 & p \end{bmatrix}$ Out[92]=

Indeed, for v = 0 we get the previously defined stress tensor:

TShow["PerfectFluid"] /. v → 0 In[93]:= PerfectFluid: $T_{\mu\nu}(t, x, y, z) = \begin{pmatrix} p & 0 & 0 & 0 \\ 0 & p & 0 & 0 \\ 0 & 0 & p & 0 \\ 0 & 0 & 0 & p \end{pmatrix}$

Multiplying a tensor by a scalar tensor (i.e. a tensor of rank 0) is also done using a "trivial" contraction with no contracted indices. For example:

Out[93]=

TShow[TCalc["SpatialDistance"[""]."Minkowski"[" $\mu\nu$ "]], "Spherical"]

Result: $\square_{\mu\nu}(t, r, \theta, \phi) = \begin{pmatrix} -r & 0 & 0 & 0 \\ 0 & r & 0 & 0 \\ 0 & 0 & r^3 & 0 \\ 0 & 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 0 & 3 \end{pmatrix}$

Out[94]=

Note the empty index string [""], which is mandatory in order for OGRe to recognize that the scalar is a tensor object. We can also multiply a scalar by another scalar:

In[95]:=

TShow[TCalc["SpatialDistance"[""]."SpatialDistance"[""]], "Spherical"]

Out[95]=

Result: \Box $(t, r, \theta, \phi) = r^2$

Now let us demonstrate some non-trivial contractions. First, we have the inner product of vectors - in this case, we get the norm (squared) of the 4-velocity, since we are contracting it with itself:

In[96]:=

TShow@TCalc["4-Velocity"[" μ "]."4-Velocity"[" μ "]]

Out[96]=

Result: (t, x, y, z) = -1

We can also contract several tensors together, with **two** matching pairs of indices:

In[97]:=

TShow@TCalc["4-Velocity"[" μ "]."PerfectFluid"[" $\mu\nu$ "]."NonSymmetric"[" $\nu\rho$ "]]

Out[97]=

Result:
$$\square_{\mu}(t, x, y, z) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ -\frac{\rho}{\sqrt{1-v^2}} \end{pmatrix}$$

Finally, to take the trace of a tensor, we simply match pairs of indices in that tensor's index string:

In[98]:=

TShow@TCalc["Minkowski"[" $\mu\mu$ "]]

Out[98]=

Result: (t, x, y, z) = 4

In[99]:=

TShow@TCalc["PerfectFluid"[" $\mu\mu$ "]]

Out[99]=

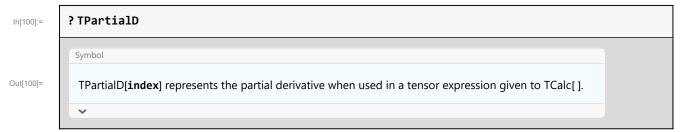

Result: $(t, x, y, z) = 3p - \rho$

Of course, this also works for tensors with more than two indices, as we will see below. Any combina-

tion of indices can be used, with no limit on the number of traces taken for each tensor.

Derivatives and curvature tensors

The **partial derivative** ∂_{μ} is represented in OGRe using the symbol **TPartialD**. It can be contracted with other tensors using the usual OGRe contraction notation - including an appropriate index string - to calculate gradients and divergences.

The **gradient** of a tensor is the partial derivative ∂_{μ} acting on the tensor with a free index, e.g. $\partial_{\mu} \phi$, $\partial_{\mu}v^{\nu}$, or $\partial_{\mu}T^{\nu\lambda}$, resulting in a tensor of **one rank higher**. For example, we can calculate the gradient $\partial_{\mu}K$ of the Kretschmann scalar as follows:

The **divergence** of a tensor is the contraction of the partial derivative ∂_{μ} with one of the tensor's indices, e.g. $\partial_{\mu}v^{\mu}$ or $\partial_{\mu}T^{\mu\nu}$, resulting in a tensor of **one rank lower**. For example, here is the divergence $\partial_{\mu} x^{\mu}$ of the spherical coordinate vector:

TShow@TCalc[TPartialD["
$$\mu$$
"]."Spherical"[" μ "]]

Out[102]=

Result: [] $(t, r, \theta, \phi) = 4$

As you can see, the syntax for both the gradient and divergence is the same; if the index specification of TPartialD["µ"] matches one of the indices of the tensor to its right, then the divergence will be calculated, otherwise the gradient will be calculated.

WARNING: When applying partial derivatives to tensors, the result generally does not transform like a tensor under a coordinate transformation. For this reason, in general relativity we normally use the **covariant derivative** instead of a partial derivative. However, there are three important exceptions, where partial derivatives must be used: in the covariant derivative itself, the Levi-Civita connection, and the Riemann tensor, all of which will be discussed below.

Of these three special cases, the covariant derivative and the Riemann tensor turn out to nonetheless transform like tensors under coordinate transformations, due to cancellations. However, the Levi-Civita connection, whose components are called the Christoffel symbols, has a special transformation rule, which is used automatically by OGRe, as we will show.

In all other cases, if the user creates an arbitrary tensor using partial derivatives, the result will generally transform incorrectly under a coordinate transformation in OGRe. Therefore, it is highly recommended to avoid using partial derivatives with TCalc unless you really know what you're doing.

The Christoffel symbols

The Christoffel symbols are a very important tensor-like objects in differential geometry. They are the components of the Levi-Civita connection, which is the unique torsion-free connection that preserves the metric. The Christoffel symbols are defined as follows:

$$\Gamma^{\lambda}_{\mu\nu} = \frac{1}{2} \mathbf{g}^{\lambda\sigma} \left(\partial_{\mu} \mathbf{g}_{\nu\sigma} + \partial_{\nu} \mathbf{g}_{\sigma\mu} - \partial_{\sigma} \mathbf{g}_{\mu\nu} \right).$$

Each of the terms inside the parentheses is a gradient of the metric, with different indices. For example, the first term $\partial_{\mu} \mathbf{g}_{v\sigma}$ is represented in OGRe as **TPartialD**[" μ "]."Metric"[" $v\sigma$ "] where "Metric" is the tensor object representing the metric. Since contraction, addition, and multiplication by scalar can be combined arbitrarily when using TCalc, we can calculate the Christoffel symbols in a straightforward way as follows:

In[103]:=

 ${\tt TList@TChangeDefaultIndices} \Big[{\tt TCalc} \Big[\frac{1}{2} \, "Schwarzschild" \, [\, "\lambda\sigma" \,] \, .$ $(\texttt{TPartialD["}\mu"]." \texttt{Schwarzschild"["}\nu\sigma"] + \texttt{TPartialD["}\nu"]." \texttt{Schwarzschild"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]." \texttt{Schwarzschild"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]." \texttt{Schwarzschild"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]." \texttt{Schwarzschild"["}\sigma\mu"]." \texttt{Schwarzschild"["}\nu"]." \texttt{Schwarzschild"["]}." \texttt{Schwarzschild"["}\nu"]." \texttt{Schwarzschild"["]}." \texttt{Sch$ TPartialD[" σ "]."Schwarzschild"[" $\mu\nu$ "]), " Γ ", {1, -1, -1}

Result:

$$\Gamma^{t}_{tr} = \Gamma^{t}_{rt} = \frac{M}{r(-2M+r)}$$

$$\Gamma^{r}_{tt} = \frac{M(-2M+r)}{r^{3}}$$

$$\Gamma^{r}_{rr} = \frac{M}{2Mr-r^{2}}$$

$$\Gamma^{r}_{\theta\theta} = 2M-r$$

$$\Gamma^{r}_{\theta\phi} = 2M-r$$

$$\Gamma^{r}_{\phi\phi} = 2M$$

Out[103]=

However, there is a problem; as we mentioned above, the Christoffel symbols are not the components of a tensor, meaning that the Levi-Civita connection does not transform as a tensor does under a coordinate transformation. Indeed, by transforming the metric in the definition, one can show that

$$\Gamma_{\mu'\nu'}^{\lambda'} = \frac{\partial \mathbf{x}^{\lambda'}}{\partial \mathbf{x}^{\lambda}} \frac{\partial \mathbf{x}^{\mu}}{\partial \mathbf{x}^{\mu'}} \frac{\partial \mathbf{x}^{\nu}}{\partial \mathbf{x}^{\nu'}} \Gamma_{\mu\nu}^{\lambda} + \frac{\partial \mathbf{x}^{\lambda'}}{\partial \mathbf{x}^{\lambda}} \frac{\partial^{2} \mathbf{x}^{\lambda}}{\partial \mathbf{x}^{\mu'} \partial \mathbf{x}^{\nu'}}.$$

The first term is the familiar transformation rule for a tensor, with one factor of the Jacobian per index as usual. However, there is also an extra second term, meaning that the Christoffel symbols do not transform like a tensor.

(Actually, you are also not supposed to raise or lower indices in the Christoffel symbols, but in practice, you can do that as long as you make it clear that it's just an abuse of notation - you are only adding factors of the metric, not creating a new tensor representation with different transformation properties.)

Due to the extra transformation term, the tensor object we calculated manually above using TCalc must not be used. Instead, we should use the built-in module TChristoffel, which not only performs the calculation automatically for us, but also marks the result as a special object with special transformation properties:

In[104]:=

Out[104]=

? TChristoffel

Symbol

TChristoffel[metricID] calculates the Christoffel symbols (the coefficients of the Levi-Civita connection) from the metric metricID and stores the result in a new tensor object with ID "metricIDChristoffel".

Note that the connection is not a tensor, and does not transform like a tensor when changing coordinates.

"metricIDChristoffel" will be a special tensor object which transforms according to the appropriate rules.

Therefore, one should only calculate the Christoffel symbols using this module. A manual calculation with

TCalc[] will result in a tensor object with the wrong transformation rules.

Let us, then, calculate the Christoffel symbols for the Schwarzschild metric properly, using TChristoffel:

In[105]:=

Out[105]=

TList@TChristoffel["Schwarzschild"]

SchwarzschildChristoffel:

$$\Gamma^{t}_{tr} = \Gamma^{t}_{rt}$$
 = $\frac{M}{r(-2M+r)}$

$$\Gamma^{r}_{tt} = \frac{M(-2M+r)}{r^3}$$

$$-r$$
 = $\frac{M}{2 M r - r^2}$

$$\Gamma^{r}_{\theta\theta} = 2M - r$$

$$\Gamma^{r}_{\phi\phi} = (2M - r) \operatorname{Sin}[\theta]^{2}$$

$$\Gamma^{\theta}_{r\theta} = \Gamma^{\theta}_{\theta r} = \Gamma^{\phi}_{r\phi} = \Gamma^{\phi}_{\phi r} = \frac{1}{r}$$

$$\Gamma^{\theta}_{\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ } = -\mathsf{Cos}[\theta] \, \mathsf{Sin}[\theta]$$

$$\Gamma^{\phi}_{\ \theta\phi} = \Gamma^{\phi}_{\ \phi\theta} = \text{Cot}[\theta]$$

These are the same components we got before, but now they will transform properly. Note that the name of the tensor object created by TChristoffel is always the name of metric with the word Christoffel appended to it (no spaces).

For maximal clarity, let us demonstrate the discrepancy in the coordinate transformation with a simple test metric:

In[106]:=

Out[106]=

TShow@TNewMetric["SimpleMetric", "Cartesian", DiagonalMatrix[{-x, 1, 1, 1}]]

SimpleMetric: $g_{\mu\nu}(t, x, y, z) = \begin{pmatrix} -x & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

We calculate its Christoffel symbols in two ways. First manually, as we did above for the Schwarzschild metric:

In[107]:=

TList@TChangeDefaultIndices

TCalc ["SimpleMetricManualChristoffel", $\frac{1}{2}$ "SimpleMetric"[" $\lambda \sigma$ "]. $(\texttt{TPartialD["}\mu"]."\texttt{SimpleMetric"["}\nu\sigma"] + \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"]."$ TPartialD[" σ "]."SimpleMetric"[" $\mu\nu$ "]), " Γ ", {1, -1, -1}

SimpleMetricManualChristoffel:

 $\Gamma^{t}_{tx} = \Gamma^{t}_{xt} = \frac{1}{2x}$

Out[107]=

Then, with the built-in module TChristoffel:

In[108]:=

Out[108]=

TList@TChristoffel["SimpleMetric"]

SimpleMetricChristoffel:

 $\Gamma^{t}_{tx} = \Gamma^{t}_{xt} = \frac{1}{2x}$

The two results have the same components, as expected. But now, let us now transform them to spherical coordinates. First, we transform the tensor object obtained using TChristoffel:

In[109]:=

Out[109]=

TList["SimpleMetricChristoffel", "Spherical"]

SimpleMetricChristoffel:

$$\begin{split} \Gamma^{t}_{\ tr} &= \Gamma^{t}_{\ rt} \\ \Gamma^{t}_{\ t\theta} &= \Gamma^{t}_{\ \theta t} \\ \Gamma^{t}_{\ t\theta} &= \Gamma^{t}_{\ \theta t} \\ \Gamma^{t}_{\ t\phi} &= \Gamma^{t}_{\ \phi t} \\ \Gamma^{r}_{\ tt} \\ \Gamma^{r}_{\ tt} \\ \Gamma^{r}_{\ \theta \theta} \\ \Gamma^{r}_{\ \theta \theta} \\ \Gamma^{r}_{\ tt} \\ \Gamma^{\theta}_{\ \theta \theta} \\ \Gamma^{\theta}_{\ \\ \Gamma$$

This is the **correct** representation of the Christoffel symbols in spherical coordinates, as the extra term in the transformation was taken into account. However, if we transform the Christoffel symbols we obtained manually using TCalc, we get:

In[110]:=

TList["SimpleMetricManualChristoffel", "Spherical"]

SimpleMetricManualChristoffel:

$$\begin{split} & \Gamma^{t}_{tr} = \Gamma^{t}_{rt} &= \frac{1}{2r} \\ & \Gamma^{t}_{t\theta} = \Gamma^{t}_{\theta t} &= \frac{\text{Cot}[\theta]}{2} \\ & \Gamma^{t}_{t\phi} = \Gamma^{t}_{\phi t} &= -\frac{\text{Tan}[\phi]}{2} \\ & \Gamma^{r}_{tt} &= \frac{1}{2} \cos[\phi] \sin[\theta] \\ & \Gamma^{\theta}_{tt} &= \frac{\cos[\theta] \cos[\phi]}{2r} \\ & \Gamma^{\phi}_{tt} &= -\frac{\text{Csc}[\theta] \sin[\phi]}{2r} \end{split}$$

Out[110]=

This is **not** the correct result, since the transformation did not take into account the extra term. To

verify that the former result is indeed the correct one, let us change the default coordinate system of **SimpleMetric** to spherical:

TChangeDefaultCoords["SimpleMetric", "Spherical"];

Now, when we calculate the Christoffel symbols manually from this metric, we will get their correct representation in spherical coordinates. This is because TCalc always performs the calculations internally in the default coordinates of the first tensor, so the result was calculated from scratch in spherical coordinates, instead of being calculated first in Cartesian coordinates and then transformed:

TList@TChangeDefaultIndices In[112]:= TCalc ["SimpleMetricManualChristoffelSpherical", $\frac{1}{2}$ "SimpleMetric"[" $\lambda \sigma$ "]. $(\texttt{TPartialD["}\mu"]."\texttt{SimpleMetric"["}\nu\sigma"] + \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"] - \texttt{TPartialD["}\nu"]."\texttt{SimpleMetric"["}\sigma\mu"]."$ TPartialD[" σ "]."SimpleMetric"[" $\mu\nu$ "]), " Γ ", {1, -1, -1}

SimpleMetricManualChristoffelSpherical:

$$\Gamma^{t}_{tr} = \Gamma^{t}_{rt} = \frac{1}{2r}$$

$$\Gamma^{t}_{t\theta} = \Gamma^{t}_{\theta t} = \frac{\cot[\theta]}{2}$$

$$\Gamma^{t}_{t\phi} = \Gamma^{t}_{\phi t} = -\frac{\tan[\phi]}{2}$$

$$\Gamma^{r}_{tt} = \frac{1}{2} \cos[\phi] \sin[\theta]$$

$$\Gamma^{r}_{\theta \theta} = -r$$

$$\Gamma^{r}_{\theta \theta} = -r$$

$$\Gamma^{\theta}_{r\theta} = \Gamma^{\theta}_{r\theta} = \Gamma^{\phi}_{r\phi} = \Gamma^{\phi}_{r\phi}$$

$$\Gamma^{\theta}_{r\theta} = \Gamma^{\theta}_{r\theta} = \Gamma^{\phi}_{r\phi}$$

$$\Gamma^{\theta}_{r\theta} = \Gamma^{\phi}_{r\theta} = \Gamma^{\phi}_{r\phi}$$

$$\Gamma^{\theta}_{r\theta} = \Gamma^{\phi}_{r\theta}$$

$$\Gamma^{\theta}_{r\theta} = \Gamma^{\phi}_{r\theta}$$

$$\Gamma^{\phi}_{r\theta} = \Gamma^{\phi}_{r\theta}$$

Indeed, this is the exact same result we got when we transformed SimpleMetricChristoffel to spherical coordinates. We have learned an important lesson: since the Christoffel symbols do not transform like a tensor, we should always use the built-in module TChristoffel to calculate them, which ensures that they transform properly. (Of course, this method is also much more convenient than writing the explicit definition...)

In[111]:=

Out[112]=

For future use, let us define the Friedmann-Lemaitre-Robertson-Walker (FLRW) metric, which describes an expanding universe:

TInitializeSymbols[a, k]; In[113]:= TShow@TNewMetric["FLRW", "Spherical", DiagonalMatrix $\left[\left\{-1, \frac{a[t]^2}{1 + r^2}, a[t]^2 r^2, a[t]^2 r^2 \operatorname{Sin}[\theta]^2\right\}\right]$ FLRW: $g_{\mu\nu}(t, r, \theta, \phi) = \begin{pmatrix} -1 & 0 & 0 \\ 0 & \frac{a[t]^2}{1-kr^2} & 0 & 0 \\ 0 & 0 & r^2 a[t]^2 & 0 \\ 0 & 0 & 0 & r^2 a[t]^2 \sin[\theta]^2 \end{pmatrix}$ Out[114]=

Here, a(t) is the **scale factor** and k is the curvature of the spatial surfaces, with k = +1, 0, -1 corresponding to positively curved, flat, or negatively curved respectively. Its Christoffel symbols can be easily calculated using TChristoffel:

TList@TChristoffel["FLRW"] In[115]:= FLRWChristoffel: $= r^2 a[t] a'[t]$ = $r^2 a[t] \operatorname{Sin}[\theta]^2 a'[t]$ $\Gamma_{tr}^{r} = \Gamma_{rt}^{r} = \Gamma_{t\theta}^{\theta} = \Gamma_{\theta t}^{\theta} = \Gamma_{t\phi}^{\phi} = \Gamma_{\phi t}^{\phi} = \frac{\alpha'[t]}{\alpha[t]}$ Out[115]= $= r\left(-1 + k r^2\right)$ $\Gamma^{r}_{\theta\theta}$ $= r(-1+kr^2)\sin[\theta]^2$ $\Gamma^{r}_{\phi\phi}$ $\Gamma^{\theta}_{r\theta} = \Gamma^{\theta}_{\theta r} = \Gamma^{\phi}_{r\phi} = \Gamma^{\phi}_{\phi r}$ = $-\cos[\theta]\sin[\theta]$ $\Gamma^{\phi}_{\theta\phi} = \Gamma^{\phi}_{\theta\theta}$ $= Cot[\theta]$

The Riemann tensor

The **Riemann curvature tensor** $R^{\rho}_{\sigma\mu\nu}$ can be calculated from the Christoffel symbols using the definition:

$$\mathbf{R}^{\rho}_{\sigma\mu\nu} = \partial_{\mu} \, \Gamma^{\rho}_{\nu\sigma} - \partial_{\nu} \, \Gamma^{\rho}_{\mu\sigma} + \Gamma^{\rho}_{\mu\lambda} \, \Gamma^{\lambda}_{\nu\sigma} - \Gamma^{\rho}_{\nu\lambda} \, \Gamma^{\lambda}_{\mu\sigma}.$$

Notice that even though it contains partial derivatives, it nonetheless transforms like a tensor under a change of coordinates, because the extra transformation terms exactly cancel each other. To calculate this tensor, we can simply write down the formula in TCalc with the correct indices contracted. Note that this time we specified the LHS indices explicitly, since they are not in the same order as the RHS indices in our definition:

In[116]:=

```
TList@TChangeDefaultIndices[TCalc["SchwarzschildRiemann"["\rho\sigma\mu\nu"],
    TPartialD["\mu"]."SchwarzschildChristoffel"["\rho v \sigma"] -
     TPartialD["\nu"]."SchwarzschildChristoffel"["\rho\mu\sigma"] +
     "SchwarzschildChristoffel"["\rho\mu\lambda"]."SchwarzschildChristoffel"["\lambda\nu\sigma"] -
     "SchwarzschildChristoffel"["\rho v \lambda"].
       "SchwarzschildChristoffel"["\lambda\mu\sigma"], "R"], {1, -1, -1, -1}]
```

SchwarzschildRiemann:

$$R^{t}_{rtr} = -R^{t}_{rrt} = -R^{t}_{\theta\theta} = -R^{t}_{\theta\theta} = -R^{r}_{\theta\theta} =$$

The Riemann tensor with all its indices down satisfies the following symmetry and antisymmetry relations:

$$R_{\rho\sigma\mu\nu} = -R_{\sigma\rho\mu\nu} = -R_{\rho\sigma\nu\mu} = R_{\mu\nu\rho\sigma}$$

Out[116]=

We can verify this for the Schwarzschild Riemann tensor using TList, as it automatically detects components that are the same up to sign:

TList["SchwarzschildRiemann", {-1, -1, -1, -1}]

SchwarzschildRiemann: = $-\frac{2M}{r^3}$ $R_{trtr} = R_{rtrt} = -R_{trrt} = -R_{rttr}$ $R_{t\theta t\theta} = R_{\theta t\theta t}$ $=\frac{M(2M-r)}{r^2}$ $R_{t\theta\theta t} = R_{\theta tt\theta}$ $= \frac{M(-2M+r)\sin[\theta]^2}{r^2}$ $R_{t\phi t\phi} = R_{\phi t\phi t}$ $= \frac{M(2M-r)\sin[\theta]^2}{r^2}$ $R_{t\phi\phi t} = R_{\phi tt\phi}$ $R_{r\theta r\theta} = R_{\theta r\theta r}$ $= \frac{M}{-2M+r}$ $R_{r\theta\theta r} = R_{\theta rr\theta}$ $= \frac{M \operatorname{Sin}[\theta]^2}{2 M - r}$ $R_{r\phi r\phi} = R_{\phi r\phi r} = -R_{r\phi\phi r}$ $R_{\theta\phi\theta\phi} = R_{\phi\theta\phi\theta} = -R_{\theta\phi\phi\theta} = -R_{\phi\theta\theta\phi} = 2 Mr Sin[\theta]^2$

Don't worry - you don't need to write the explicit definition of the Riemann tensor every time we want to calculate it. Instead, OGRe offers the built-in module TRiemannTensor:

? TRiemannTensor

TRiemannTensor[metricID] calculates the Riemann tensor from the metric metricID and stores the result in a new tensor object with ID "metricIDRiemann".

If a tensor with ID "metricIDChristoffel" exists, it will be assumed to be the Christoffel symbols of the metric, and will be used in the calculation. Otherwise, "metricIDChristoffel" will be created using TChristoffel[].

For example, for the FLRW metric we get:

 $R_{\sigma rr\sigma}$

In[117]:=

Out[117]=

In[118]:=

Out[118]=

In[119]:=

Out[119]=

TList@TRiemannTensor["FLRW"]

FLRWRiemann:

$$\begin{array}{lll} R^{t}_{rtr} & = & \frac{a[t]a''[t]}{1-kr^2} \\ R^{t}_{rrt} & = & \frac{a[t]a''[t]}{1-kr^2} \\ R^{t}_{\theta t \theta} = -R^{t}_{\theta \theta t} & = & r^2 a[t]a''[t] \\ R^{t}_{\phi t \phi} = -R^{t}_{\phi \phi t} & = & r^2 a[t] \sin[\theta]^2 a''[t] \\ R^{r}_{ttr} = R^{\theta}_{tt\theta} = R^{\phi}_{tt\phi} = -R^{r}_{trt} = -R^{\theta}_{t\theta t} = -R^{\phi}_{t\phi t} & = & \frac{a''[t]}{a[t]} \\ R^{r}_{\theta r \theta} = R^{\phi}_{\theta \phi \theta} = -R^{r}_{\theta \theta r} = -R^{\phi}_{\theta \theta \phi} & = & r^2 \left(k + a'[t]^2\right) \\ R^{r}_{\phi r \phi} = R^{\theta}_{\phi \theta \phi} = -R^{r}_{\phi \phi r} = -R^{\theta}_{\phi \theta \theta} & = & r^2 \sin[\theta]^2 \left(k + a'[t]^2\right) \\ R^{\theta}_{rr\theta} = R^{\phi}_{rr\phi} & = & \frac{k + a'[t]^2}{1-kr^2} \\ R^{\theta}_{r\theta r} = R^{\phi}_{r\phi r} & = & \frac{k + a'[t]^2}{1-kr^2} \end{array}$$

Using **TRiemannTensor** also has the advantage that it takes a metric as an input, and will automatically calculate the Christoffel symbols of the metric using **TChristoffel** if they have not already been calculated. The same principle also applies to the other built-in modules for calculating curvature tensors, which we will present below; they always take a metric as input, and will calculate any intermediate tensors in their definitions automatically as needed.

Finally, recall that above, we gave the **Kretschmann scalar** for the Schwarzschild metric as an example of a scalar. Now that we have the Riemann tensor, and the ability to contract tensors, we can actually calculate the Kretschmann scalar from scratch. The formula is:

$$K = R_{\rho\sigma\mu\nu} R^{\rho\sigma\mu\nu}$$

so it can be easily calculated in OGRe as follows:

In[120]:=

Kretschmann: K $(t, r, \theta, \phi) = \frac{48 M^2}{r^6}$

Out[120]=

The Ricci tensor and scalar

The **Ricci tensor** $R_{\mu\nu}$ is the trace of the first and third indices of the Riemann tensor:

$$R_{\mu\nu} = R^{\lambda}_{\mu\lambda\nu}$$
.

Therefore, we can calculate it by taking the trace, with the usual TCalc syntax. For the Schwarzschild metric, the Ricci tensor vanishes:

In[121]:=

TList@TCalc["SchwarzschildRiemann"[" $\lambda\mu\lambda\nu$ "], "R"]

Result:

Out[121]=

No non-zero elements.

We can also use the shorthand module TRicciTensor:

In[122]:=

? TRicciTensor

Symbol

TRicciTensor[metricID] calculates the Ricci tensor from the metric metricID and stores the result in a new tensor object with ID "metricIDRicciTensor".

Out[122]=

If a tensor with ID "metricIDRiemann" exists, it will be assumed to be the Riemann tensor of the metric, and will be used in the calculation. Otherwise, "metricIDRiemann" will be created using TRiemannTensor[].

Here is the Ricci tensor for the FLRW metric:

In[123]:=

TList@TRicciTensor["FLRW"]

FLRWRicciTensor:

$$R_{tt} = -\frac{3 a''[t]}{a[t]}$$

$$R_{rr} = \frac{2 (k+a'[t]^2) + a[t] a''[t]}{1-k r^2}$$

$$R_{\theta\theta} = r^2 (2 (k+a'[t]^2) + a[t] a''[t])$$

$$R_{\phi\phi} = r^2 \sin[\theta]^2 (2 (k+a'[t]^2) + a[t] a''[t])$$

Out[123]=

The **Ricci scalar** is the trace of the Ricci tensor:

$$\mathbf{R} = \mathbf{R}_{\lambda}^{\lambda} = \mathbf{g}^{\mu\nu} \mathbf{R}_{\mu\nu}$$
.

We can calculate it from the Ricci tensor by taking the trace:

In[124]:=

TShow@TCalc["FLRWRicciTensor"[" $\mu\mu$ "], "R"]

Out[124]=

Result: R
$$(t, r, \theta, \phi) = \frac{6(k + a'[t]^2 + a[t]a''[t])}{a[t]^2}$$

Or, as usual, we can simply use the shorthand module TRicciScalar to calculate it directly from the metric:

In[125]:=

? TRicciScalar

Symbol

Out[125]=

TRicciScalar[metricID] calculates the Ricci scalar from the metric metricID and stores the result in a new tensor object with ID "metricIDRicciScalar".

If a tensor with ID "metricIDRicciTensor" exists, it will be assumed to be the Ricci tensor of the metric, and will be used in the calculation. Otherwise, "metricIDRicciTensor" will be created using TRicciTensor[].

In[126]:=

TList@TRicciScalar["FLRW"]

FLRWRicciScalar:

Out[126]=

$$R = \frac{6(k+a'[t]^2+a[t]a''[t])}{a[t]^2}$$

The Einstein tensor

The **Einstein tensor** G_{uv} is given by:

$$G_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R.$$

As with all other curvature tensors, we can calculate it by combining the previously calculated tensors with the usual syntax:

Out[127]=

TList@TCalc["FLRWRicciTensor"[" $\mu\nu$ "] - $\frac{1}{2}$ "FLRW"[" $\mu\nu$ "]."FLRWRicciScalar"[""], "G"]

Result:

$$G_{tt} = \frac{3(k+a'[t]^2)}{a[t]^2}$$

$$G_{rr} = \frac{k+a'[t]^2+2a[t]a''[t]}{-1+kr^2}$$

 $G_{\theta\theta} = -r^2 \left(k + a'[t]^2 + 2 a[t] a''[t] \right)$

 $G_{\phi\phi} = -r^2 \sin[\theta]^2 (k + a'[t]^2 + 2 a[t] a''[t])$

Or we can use the built-in module **TEinsteinTensor**:

In[128]:=

? TEinsteinTensor

Symbol

TEinsteinTensor[metricID] calculates the Einstein tensor from the metric metricID and stores the result in a new tensor object with ID "metricIDEinstein".

Out[128]=

If a tensor with ID "metricIDRicciTensor" exists, it will be assumed to be the Ricci tensor of the metric, and will be used in the calculation. Otherwise, "metricIDRicciTensor" will be created using TRicciTensor[].

In[129]:=

Out[129]=

TList@TEinsteinTensor["FLRW"]

FLRWEinstein:

$$G_{tt} = \frac{3(k+a'[t]^2)}{a[t]^2}$$

$$G_{rr} = \frac{k+a'[t]^2+2a[t]a''[t]}{-1+kr^2}$$

$$G_{\theta\theta} = -r^2 (k + a'[t]^2 + 2 a[t] a''[t])$$

$$G_{\phi\phi} = -r^2 \sin[\theta]^2 (k + a'[t]^2 + 2 a[t] a''[t])$$

Covariant derivatives

The partial derivative has limited use in general relativity, as it does not transform like a tensor. Therefore, it is only used in special cases, such as calculating the Christoffel symbols and the Riemann tensor. The **covariant derivative** ∇_{μ} is a generalization of the partial derivative, which does transform

like a tensor (as long as it acts on a proper tensor). It is defined as follows:

- On a scalar Φ , the covariant derivative acts as $\nabla_{\mu}\Phi \equiv \partial_{\mu}\Phi$.
- On a vector v^{μ} , the covariant derivative acts as $\nabla_{\mu}v^{\nu} \equiv \partial_{\mu}v^{\nu} + \Gamma^{\nu}_{\nu\lambda}v^{\lambda}$.
- On a covector w_{μ} , the covariant derivative acts as $\nabla_{\mu} w_{\nu} \equiv \partial_{\mu} w_{\nu} \Gamma^{\lambda}_{\mu\nu} u_{\lambda}$.

More generally, on a rank (p, q) tensor with components $T_{\sigma_1 \cdots \sigma_q}^{\nu_1 \cdots \nu_p}$, the covariant derivative $\nabla_{\mu} T_{\sigma_1 \cdots \sigma_q}^{\nu_1 \cdots \nu_p}$ is defined as follows:

- The first term will be $\partial_{u}T_{\sigma_{1}\cdots\sigma_{n}}^{\nu_{1}\cdots\nu_{p}}$.
- We **add** one term $\Gamma^{v_i}_{\mu\lambda} T^{v_1 \cdots \lambda \cdots v_p}_{\sigma_1 \cdots \sigma_q}$ for each upper index v_i .
- We **subtract** one term $\Gamma^{\lambda}_{\mu\sigma_i} T^{\nu_1 \cdots \nu_{\rho}}_{\sigma_1 \cdots \lambda \cdots \sigma_q}$ for each lower index σ_i .

Note that even though the covariant derivative is made from ingredients that do not transform like tensors - the partial derivative and the Christoffel symbols - the unwanted terms in the transformations of these ingredients cancel each other exactly, so that in the end, the entire sum does transform like a tensor.

As usual, we can, of course, write down the covariant derivative manually. For example, the covariant divergence of the metric is:

$$\nabla_{\mu} \mathbf{g}_{\alpha\beta} = \partial_{\mu} \mathbf{g}_{\alpha\beta} - \Gamma^{\lambda}_{\mu\alpha} \mathbf{g}_{\lambda\beta} - \Gamma^{\lambda}_{\mu\beta} \mathbf{g}_{\alpha\lambda}.$$

It should vanish, by definition, for any metric; this is what we meant when we said the Levi-Civita connection **preserves** the metric. Indeed, we have for the Schwarzschild metric:

In[130]:=

```
TList@TCalc[TPartialD["\mu"]."Schwarzschild"["\alpha\beta"] -
    "SchwarzschildChristoffel"["\lambda\mu\alpha"]."Schwarzschild"["\lambda\beta"] -
    "SchwarzschildChristoffel"["\lambda\mu\beta"]."Schwarzschild"["\alpha\lambda"]]
```

Result:

No non-zero elements.

Out[130]=

Much more conveniently, the covariant derivative is represented in OGRe as TCovariantD. It will automatically add the correct terms, as detailed above, for each of the tensor's indices. To use it, simply contract it with any tensor, just like TPartialD:

In[131]:=

? TCovariantD

Symbol

TCovariantD[index] represents the covariant derivative when used in a tensor expression given to TCalc[]. If a tensor with ID "metricIDChristoffel" exists, where metricID is the metric associated with the tensor the derivative is acting upon, then it will be assumed to be the Levi-Civita connection of the metric, and will be used in the calculation. Otherwise, "metricIDChristoffel" will be created using TChristoffel[].

Out[131]=

For example, we can check that the covariant derivative of the FLRW metric also vanishes:

In[132]:=

TList@TCalc[TCovariantD["
$$\mu$$
"]."FLRW"[" $\alpha\beta$ "]]

Result:

Out[132]=

No non-zero elements.

The covariant divergence of the Einstein tensor is:

$$\nabla_{\mu} \mathbf{G}^{\mu\nu} = \partial_{\mu} \mathbf{G}^{\mu\nu} + \Gamma^{\mu}_{\mu\lambda} \mathbf{G}^{\lambda\nu} + \Gamma^{\nu}_{\mu\lambda} \mathbf{G}^{\mu\lambda} = \mathbf{0}.$$

Note that it involves a contraction in the index μ , which becomes a trace in the first Christoffel symbol. This expression vanishes because of the **Bianchi identity**:

$$\nabla_{\mu} \mathbf{R}^{\mu \nu} - \frac{1}{2} \nabla^{\nu} \mathbf{R} \rightarrow \nabla_{\mu} \mathbf{G}^{\mu \nu} = \mathbf{0}.$$

To calculate it in OGRe, we simply write:

In[133]:=

TList@TCalc[TCovariantD[" μ "]."FLRWEinstein"[" $\mu\nu$ "]]

Result:

Out[133]=

No non-zero elements.

Finally, for a non-trivial result, let us recall that the stress-energy tensor should be conserved:

$$\nabla_{\mu} \mathbf{T}^{\mu\nu} = \partial_{\mu} \mathbf{T}^{\mu\nu} + \Gamma^{\mu}_{\mu\lambda} \mathbf{T}^{\lambda\nu} + \Gamma^{\nu}_{\mu\lambda} \mathbf{T}^{\mu\lambda} = \mathbf{0}.$$

This follows from the fact that $\nabla_{\mu} \mathbf{G}^{\mu\nu} = \mathbf{0}$, combined with the **Einstein equation**:

$$G_{\mu\nu} = \kappa T_{\mu\nu}$$

where $\kappa = 1$ or $\kappa = 8 \pi$ depending on your preferred units. However, unlike $\nabla_{\mu} \mathbf{G}^{\mu\nu} = \mathbf{0}$, the relation $\nabla_{\mu} T^{\mu\nu} = 0$ is **not** an identity; it is an **energy-momentum conservation equation**. To derive the equation for the FLRW metric, let us first define the rest-frame fluid 4-velocity in this spacetime:

In[134]:=

Out[134]=

TShow@TNewTensor["RestVelocity", "FLRW", "Spherical", {1}, {1, 0, 0, 0}, "u"]

RestVelocity:
$$u^{\mu}(t, r, \theta, \phi) = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

Using the 4-velocity and the metric, we redefine the perfect fluid stress tensor in the FLRW spacetime using the formula $T^{\mu\nu} = (\rho + p) u^{\mu} u^{\nu} + pg^{\mu\nu}$, and give ρ and p spacetime dependence:

In[135]:=

TCalc["PerfectFluid", $(\rho[t, r, \theta, \phi] + p[t, r, \theta, \phi])$ "RestVelocity"[" μ "]."RestVelocity"[" ν "] + p[t, r, θ , ϕ] "FLRW"[" $\mu\nu$ "], "T"]; TChangeDefaultIndices["PerfectFluid", {1, 1}]; TShow["PerfectFluid"]

Out[136]=

$$(\rho[t, r, \theta, \phi] \quad 0 \quad 0 \quad 0)$$
 $0 \quad \frac{(1-kr^2)\rho[t,r,\theta,\phi]}{a[t]^2} \quad 0 \quad 0$
 $0 \quad \frac{\rho[t,r,\theta,\phi]}{r^2a[t]^2} \quad 0$

PerfectFluid: $T^{\mu\nu}(t, r, \theta, \phi) =$

Finally, we take the covariant derivative of the stress tensor:

TList@TCalc["FLRWConservation", TCovariantD["
$$\mu$$
"]."PerfectFluid"[" $\mu\nu$ "]]

FLRWConservation:

$$\Box^{t} = \frac{3 (p[t,r,\theta,\phi]+\rho[t,r,\theta,\phi]) \ a'[t]}{a[t]} + \rho^{(1,0,0,0)}[t,r,\theta,\phi]$$
Out[137]=

$$\Box^{r} = \frac{(1-k \ r^{2}) p^{(0,1,0,0)}[t,r,\theta,\phi]}{a[t]^{2}}$$

$$\Box^{\theta} = \frac{p^{(0,0,1,0)}[t,r,\theta,\phi]}{r^{2} \ a[t]^{2}}$$

$$\Box^{\phi} = \frac{\operatorname{Csc}[\theta]^{2} p^{(0,0,0,1)}[t,r,\theta,\phi]}{r^{2} \ a[t]^{2}}$$

From demanding that the t component vanishes, we get the following equation:

$$\dot{\rho} = -3 (\rho + p) \frac{\dot{a}}{a}.$$

We see that in an expanding universe, energy is not conserved, but rather, the energy density changes with time in a way that depends on the scale factor. If the universe is not expanding, that is, $\dot{a} = 0$, then energy will be conserved.

Additional information

Compatibility

This package is compatible with Mathematica 12.0 or newer, on any platform (Windows, Linux, and Mac). It should also run on Mathematica 11 or 10, but that has not been tested. The package will not work on versions prior to Mathematica 10, due to extensive use of Association, which was introduced in Mathematica 10.0.

Version history

For the full version history, please see the file **README.md** in the GitHub repository.

Future plans

The following features are currently planned for future versions:

- Get a subset of a tensor's components by replacing one or more indices with a specific coordinate, e.g. T^{012} will return that component and $T^{\mu\nu0}$ will return a rank-2 tensor.
- More control over the output style of TShow and TList.
- More modules to calculate commonly-used curvature tensors, such as the Kretschmann scalar and the Weyl tensor.
- Parallelization of various operations for increased performance.
- Comma and semicolon operators as alternatives to TPartialD and TCovariantD.
- TShow["ID"["indices"]] should use the given indices when showing the tensor, instead of the default indices.
- Expressions like TCalc ["A"+"B"] or TCalc ["A"."B"] should automatically deduce the indices to use if possible.
- Use Mathematica symbols, instead of strings, as tensor IDs for less cluttered syntax and autocompletion.
- Improve performance of raising and lowering indices by doing them all at once instead of index by index.

- Support for connections with torsion.
- Support for frame fields (a.k.a. tetrads or vierbeins).
- If three coordinate systems are defined, and we know how to get from 1 to 2 and from 2 to 3, then OGRe should automatically deduce the transformation from 1 to 3.
- Display the metric as a line element.
- TCalc should display the equation being calculated in index notation.
- Support for 3+1 decomposition.
- Derive the geodesic equation from a given metric.
- And much more...

If you would like a request any additional features, or if you encounter any bugs, please feel free to open a new issue on GitHub!
